Cost of English tubbing varies with the price of pig iron, etc., from 5*l.* to 7*l.* 10*s.* per ton ; putting in the tubbing costs 2*l.* to 2*l.* 10*s.* per ton of tubbing put in, or 5*l.* to 7*l.* per fathom of shaft. The following are the detailed costs of tubbing a 15 ft. shaft with 12 segments to the ring, 2 ft. deep, ¾ in. thick, each ring weighing 2 tons 10 cwt. :—

	£	*s.*	*d.*
Three rings, 7 tons 10 cwt. at 7*l.* 10*s.*	56	5	0
Sheeting, 213 ft. at 8*s.* per 100	0	17	0
Wedges, 3,500 at 10*s.* per 1,000	1	15	0
Labour, putting in and wedging	6	0	0
Total	64	17	0
Cost per fathom, about	64	0	0

To the above must be added a due proportion of the wedging curb. The castings for the curb of a 15-ft. shaft cost 25*l.* to 35*l.*, sheeting and wedges 5*l.*, putting in and wedging 10*l.* to 15*l.* Dressing the curb seat may cost from 10*l.* to 40*l.* according to circumstances. About ten men are usually employed in the shaft in wedging tubbing, and they can wedge two to three rings per shift.

The cost of 'German' tubbing usually comes out a little less than English tubbing per fathom. The seams and joints are all machined, this costing 3*l.* 10*s.* to 4*l.* per ring; three shifts of four men can put in and bolt up four rings (20 to 24 ft.) per 24 hours.

The cost of 'German' tubbing in an 18-ft. shaft, the tubbing being 1 in. to 1½ in. thick, 12 segments to the ring 5 ft. deep, was as follows in this country :—

	£	*s.*	*d.*	
Cast-iron tubbing, 13 tons 4 cwt. at 7*l.* 10*s.* .	99	0	0	per fathom
Lead for sheeting and washers, 6 cwt. . .	6	0	0	
Bolts and nuts	3	5	0	
Labour	7	10	0	
Cost per fathom	115	15	0	

In the Minister Achenbach Colliery a shaft 17 ft. in diameter was tubbed with 18 rings of tubbing 8 ft. 2 ins. high, 1 in. to 1¼ in. thick, each ring composed of 10 segments. The weights of material employed were :—

Tubbing . . .	192 tons 10 cwt.	Lead washers . . .	1 ton 2 cwt.
Lead strips . .	2 „ 8 „	Bolts, nuts and washers .	6 „ 3 „

Where the ground is weak and apt to run, suspended tubbing can be used to much advantage. This method was used at Astley Green (*Trans. Inst. M. E.* xxxix. p. 543), also at Hamsterley (*Trans. Inst. M. E.* xxxviii. p. 320); the latter shaft was 10 ft. in diameter and 35 ft. deep. The cost was :—

Materials, 627*l.* 2*s.* 10*d.*, labour, 141*l.* 0*s.* 3*d.*, equal to 83*l.* 16*s.* per fathom. The method is to be recommended for safety, speed and economy.

The above, which may be called ordinary methods of sinking, can only be used where a moderate influx of water has to be contended with; the greatest quantity ever dealt with by these means has been in the sinkings at Blackhall Rocks, where the Horden Colliery Company has sunk two shafts through the Magnesian Limestone in which 14,300 gallons per minute were being pumped from a depth of about 90 yards. Very much less than this is generally sufficient to cause special methods to be resorted to, 5,000 gallons per minute being generally considered prohibitive. The increase of cost due to a heavy flow of water in deep sinkings is well shown by a table of estimated costs of sinking in wet ground in Westphalia :—

Costs of Sinking Shafts 16 to 17 Ft. in Diameter in Westphalia per Fathom.

To Depth of	Where the Average Flow of Water is	
	880 Gallons per Minute.	1,760 Gallons per Minute.
Fathoms.	£	£
27	458	548
55	566	750
82	686	960
110	804	1,170
137	914	1,316
164	1,006	1,554
219	1,188	1,920
273	1,316	2,286
328	1,554	2,652

(*L. Hoffman*, 'Glückauf,' xxxvii. p. 775.)

Cost of Shaft Sinking in Gold Mines.

A shaft 4 ft. by 8 ft. in clear can be sunk in California, where wages are 14*s.* per shift, by hand drilling, at a cost of 4*l.* 10*s.* per foot. This includes labour, timbering, explosives and supplies. The hoisting done by a horse whim and no water to pump. The rate of progress is about one foot per day.

In Nevada a shaft 4 ft. by 8 ft. in clear was sunk 100 ft. in 31½ days by means of hand drilling. The cost per foot was 6*l.* 10*s.* Labour 16*s.* per shift.

Large Shafts.—In Western Australia shafts vary from 4 ft. by 10 ft. to 5½ ft. by 13½ ft. On eleven of the mines in the district the cost per foot of shaft is from 11*l.* to 16*l.*, and from 2*s.* 9*d.* to 5*s.* 6*d.* per cub. foot of material excavated. The average monthly advance was 34 ft. to 60 ft. with an average of 50 ft. Machine drills used on all above shafts.

In Utah, with wages 12*s.* per shift, a shaft 17 ft. by 65 ft. was sunk in ground of medium hardness at a cost of 12*l.* per foot sunk or 1*l.* 16*s.* per ton of material broken. Machine drills used. Pumping from 300 ft. Rate of sinking 0·9 ft. per day.

On the Rand a shaft (Brakpan, Ltd.) 43 ft. by 9 ft. in the clear was sunk at a rate of 204 ft. per month. The working cost was 14*l.* 10*s.* per foot and the total cost 22*l.* 14*s.* per foot. Ground soft. Hand drilling employed.

The following are some of the Rand shafts and the cost per ton of material handled :—

Shaft.	Size.	Speed per Month.	Cost per Ton.	Method Employed.
			s. *d.*	
Rand Collieries . .	34 ft. by 9 ft.	120 ft.	10 9	Machine
Kleinfontein . .	34 ft. by 9 ft.	107 ft.	11 8	,,
Brakpan . . .	43 ft. by 9 ft.	124 ft.	8 11	Hand.
City Reef . . .	46 ft. by 9 ft.	125 ft. 6 ins.	9 2	,,
Hercules . . .	47 ft. by 9 ft.	119 ft.	8 5	,,
Wolhunter . . .	46 ft. by 9 ft.	95 ft.	10 6	,,

The Inspiration Copper Company, Miami, Arizona, sunk and completed a shaft 12 ft. 4 in. by 16 ft. 8 in., 1,400 ft. deep in 10 months.

Some exceptionally fast sinking has been done on the Rand ; thus, in one of the shafts on the Crown Mines 318 ft. were sunk in August, 1925, and in one on the Randfontein Estates 386 ft. were sunk in June 1926.

Ferro-concrete Tubbing.

(The François Cementation Co., Ltd., Bently, Doncaster.)

Ferro-concrete tubbing of monolithic construction is rapidly supplanting cast-iron tubbing as shaft lining. As compared with cast-iron tubbing the cost is, roughly, the same for the first 75 yds. in depth, but thereafter it becomes relatively very much cheaper. Other advantages are that it does not corrode, does not require wedging, repairing, or renewing, but increases in strength with age ; with great inertia it has great flexibility ; it is not appreciably affected by temperature variations, and it is easily adaptable to change of size while sinking. The cost of ferro-concrete tubbing, to resist a static pressure of 250 lbs. to the sq. in., with a safety factor of 2 to 3·5 for an 18-ft. diameter shaft, is calculated at 65*l.* per lineal yard.

Winzing and Raising.

At Park City, Utah, winzes 11 ft. by 7·5 ft. in quartzite are sunk at a cost of 6*l.* per foot sunk, or 1*l.* 10*s.* per ton of material broken. The advance is about 1 ft. per day. In same mine raises, 17·5 ft. by 5·5 ft., are put up at a cost of 1*l.* 14*s.* per foot or 4*s.* per ton of material broken. The advance is at the rate of 3·3 ft. per day.

In Western Australia winzes are from 4 to 5 ft. in width and 6 to 8 ft. long. They are 50 ft. to 200 ft. deep, and the average total cost per foot in eleven of the mines is 4*l.* 15*s.*

The rises in the same district extend from 25 ft. to 120 ft. in height, and are 4 ft. to 5 ft. wide and 6 ft. to 8 ft. long. The total cost on the average is 3*l.* 18*s.* 7*d.* per foot.

Special Methods of Sinking.

In hard, very wet ground :—

Kind-Chaudron : maximum diameter of shaft, 15 ft. ; greatest depth yet attained by it, 1,335 ft. ; Nos. 1 and 2 pits Marsden Colliery (the first sunk in this country by this method) cost respectively 362*l.* 8*s.* and 293*l.* per fathom ; in the North of France shafts 8 to 12 ft. diameter to depth of 100 fathoms cost 80*l.* to 240*l.* per fathom, and the rate of sinking varied from 2 to 6 fathoms per month. In Germany it is estimated that to sink 55 fathoms by this process at a depth of about 300 fathoms would cost about 1,400*l.* per fathom for a shaft 14 ft. 6 ins. in diameter. (See *Bull. Ind. Min.*, 1909, ser. 4, vol. ii, p. 342.

Poetsch Freezing Process.—Applicable both to fissured firm ground and to running ground. The brine used is a 25 per cent. solution of magnesium chloride cooled down to —20°C., its freezing point being about —35°C. The following table shows the pressures at which ammonia gas liquefies at different temperatures :—

Temperatures.		Pressures in Lbs. per Sq. In.
—20°C.	— 4°F.	27
—10°C.	+14°F.	41
0°C.	+32°F.	62
+10°C.	+50°F.	89
+20°C.	+68°F.	125

It is estimated that to produce 100,000 negative calories per hour at —15° C., 50-60 h.p. are required at the freezing plant, and that 0·25 lb. of ammonia and 2 gallons of brine are required for each yard in length of the freezing circuit.

Saturated sand (165 parts water to 1,000 parts sand) frozen at 32° F. has a crushing strength of 242–341 lbs. per sq. in., and at — 13° F. of 2,845 lbs. per sq. in.

Shafts have been sunk to 130 fathoms by this method, the cost for shafts 13 ft. to 16 ft. in diameter ranging from about 150*l.* to 250*l.* per fathom. The cost of sinking two pits, 12 ft. and 16 ft. 6 ins. respectively in diameter, at Anzin, in 1895, to a depth of 50 fathoms, was as follows :—

	£ s. d.	£ s. d.
Cost of freezing plant	. .	73 2 0
Cost of freezing operations . .	. .	48 6 0
Cost of sinking and tubbing : labour .	32 16 0	
Cost of tubbing . . .	66 10 0	
		99 6 0
Total cost per fathom		220 14 0

The cost of sinking a pair of 20 ft. shafts by freezing under ordinary conditions should be :—

	£
To a depth of 50 fathoms	17,500
„ „ 100 „	28,000
„ „ 200 „	50,000

(*W. W. Wilson*, Tr. Inst. M.E. xli. 353.)

Freezing an 18-ft. shaft at Monkwearmouth cost 230*l.* per fathom to a depth of 60 fathoms.

A deep sinking was carried out by this process at Beeringen in 1920 ; a depth of 1,640 ft. of clay, quicksand, and water-bearing chalk was first sunk through in this way, and subsequently the process was applied to the more difficult task of passing through a bed of running sand 46 ft. thick, at a depth of 2,000 ft. under a pressure of 926 lbs. to the sq. in.

(*Annales des Mines*, Ser. xi., vol. ix., 1920, Pt. I. p. 5.)

At Seaham, Co. Durham, there were three freezing units, one of 300,000 negative calories and two of 150,000 negative calories each per hour (300 and 150 h.p. respectively). There were five double-acting brine pumps 10 in. diam., 10-in. stroke ; the brine was calcium chloride solution of sp. gr. 1·25. Two shafts have been sunk 21 ft. diam. in the clear to a depth of about 490 ft. (See 'The Sinking of Londonderry Colliery, Seaham Harbour, Co. Durham, by the Freezing Process,' by J. L. Henrard and J. T. Whetton, *Trans. Inst. Min. Eng.*, vol. lxxv., 1928, p. 358).

In the sinking of No. 19 pit at Courrières in 1909, which was sunk by the freezing method, difficulties were encountered in the upper part of the shaft owing to running water, and these were overcome by the injection of cement to a depth of 57 ft. ; over 1,000 tons of cement were used. (*Annales des Mines*, Ser. xi., vol. ix., 1920, Pt. I. p. 38.)

In sinking through strata containing brine, *e.g.* in certain potash mines, the temperature must be reduced below —35° C. Liquid carbonic acid must be used instead of ammonia in the freezing plant and calcium chloride brine. (*Glückauf*, vol. 63, 1927, p. 293.)

Sheet piling can be used for relatively shallow sinking, near the surface. At Bowburn Colliery Co., Durham, 6 fathoms of wet sand were sunk through by wooden piles in 1906 at a cost of 26*l.* per fathom for timber and 34*l.* 10*s.* for labour. Interlocking steel piling (p. 504) of joists of various forms has also been used.

The dropshaft method is employed in various forms, sometimes by weighting a cutting shoe and curb, on which an iron or brickwork cylinder is built up, or more usually by building a brick or concrete pressure block against which work hydraulic rams that force down tubbing of cast iron, or in exceptionally difficult cases of cast steel. The former method (forcing down a shoe by dead-weight) was found much superior to forcing a shoe down by jacks in sinking a shaft 14 ft. by 8 ft. through 70 ft. of loose strata at Des Moines, Iowa (*Trans. Amer. Inst. Min. Eng.*, vol. lv., p. 232). The following table shows probable costs for shafts of normal size in ordinary running ground (Hoffman) :—

For depth.	Cost per fathom sunk.	For depth.	Cost per fathom sunk.
	£		£
From 15 fathoms to 27 fathoms .	320	From 82 fathoms to 110 fathoms .	1,280
„ 27 „ to 55 „ .	732	„ 110 „ to 137 „ .	1,554
„ 55 „ to 82 „	1,006	„ 137 „ to 165 „ .	1,830

A sinking with a timber drop shaft lining is described in the February, 1922, *Bulletin of the Canadian Institute of Mining and Metallurgy.*

The *Honigmann* system has been used in a few cases down to depths of 70 fathoms on the Continent; the shaft is bored out by a dredge-borer, the walls being kept up by internal hydrostatic pressure, and the shaft is lined with tubbing composed of rings of channel iron riveted together and subsequently lined with concrete.

Cement Injections.—The Sonnenschein cementation process for sinking through quicksands consists in boring a number of holes about 5 m. deep, relatively close together, through the concrete plug in the shaft bottom. When a sufficient number of holes have been bored, water is forced down a bore-hole adjoining the one to be treated, thus forcing the quicksand up the latter, and leaving a conical cavity in the quicksand below the plug. Cement slurry is then forced down the borehole to be treated until the cavity previously formed is filled with cement, and the operation is repeated until a continuous body of cement, about 5 m. deep, is formed below the plug. The cement is then excavated until only enough is left to form a fresh plug, and the entire operation is repeated until the quicksand has been traversed.

The François Cementation Process.

(The François Cementation Co., Ltd., Bentley, Doncaster.)

The origin of the use of cement grout in mine shafts is not certain. Probably the first fully authenticated use was in the injection behind shaft lining at the Rheinpreussen shaft, near Homberg, in 1864, at a pressure of 210 lbs. to the square inch. Monsieur H. Portier at Courrières in 1900 successfully injected and sealed a considerable feeder of water behind an old shaft lining of wood. Cement injection was successfully employed at a shaft sinking in Germany by R. A. Weide, at Pohlhauer, Saxony, in 1901. Early examples of its use in France were by Monsieur Reumaux at Lens; and by Monsieur Deffieux at the Mine de Marles in 1908. In 1911 Mr. Albert J. François, who had previously spent some years on the Continent in experimenting with various systems of cement injection behind shaft lining and through various classes of strata, introduced his process in England, where its possibilities were at once recognised by colliery engineers, and where Mr. François was given every opportunity to improve his patents and develop his process. Over the previous crude systems his methods were as distinctive and advanced as their success was marked, and his process proved a valuable aid to the development and maintenance of coal mines in wet areas.

The process has since been introduced into France, Belgium, Germany, and South Africa, where it is extensively used. In all, forty shafts have been sunk by its means. The preliminary silicatisation of the ground, which is an essential part of the process, was first tried at Hatfield Main, in 1911, with complete success. In porous or finely fissured strata, or alluvial deposits, or generally where the injection of cement slurry proves difficult, the preliminary preparation of the ground by the injection of solutions of silicate of soda and sulphate of alumina is used; the shaft is sunk by ordinary methods until the presence of water is indicated by means of test holes. A number of holes are then bored in the shaft bottom, pipes being cemented in them, their number, position, and inclination being dependent upon the size of the shaft and the character of the strata. Through these pipes boreholes are sunk by means of a diamond drill. On the tapping of feeders by one of the holes the boring is immediately stopped and the pipe in the hole connected by means of a length of high pressure flexible hose to a column of pipes in the shaft, leading in turn to a cement pump and mixing tank on the surface. The holes are arranged in series for cementation and silicatisation, and into them cement pulp and mixtures of chemicals are pumped, the strength and proportion of the mixtures of chemicals, the percentage of cement, and the pressure employed being such as experience has shown to be best suited to the class of strata and pressure of water to be treated. The holes are cleaned out and reinjected or further deepened as necessary, the process being repeated with the various holes, boring and injecting of the different holes taking place simultaneously. The ground is treated in this manner until the desired length of ground has been rendered sufficiently watertight to allow mining and walling operations to proceed. The ground is excavated in the ordinary manner and reinforced concrete walling built up, any water not sealed off by the cementation of the boreholes being shut off by injections between the completed lining and the ground. On the walling being completed a second length of ground is excavated and walled, this procedure being continued till the water-bearing strata have been passed through. The lining employed through water-bearing or bad ground is ferro-concrete tubbing of monolithic construction. Cementation in ordinary ground will cost about 50*l.* per yard for a 20-ft. shaft (see *Transactions of Mining Engineers*, vol. liii., 1916, p. 22).

The process has been used in sinking a shaft 16 ft. in diameter at the Holditch Iron Mine, Chesterton, Staffs. The shaft is sunk through the water-bearing Keele strata to a depth of 632 ft., the upper bed giving off 30,000 gallons of water per hour. The total time occupied was 69 weeks, and the costs were 40*l.* 4*s.* 4*d.* for labour and 36*l.* 3*s.* 9*d.* for material per yard of finished shaft (1916–17), or together 76*l.* 8*s.* 1*d.*; it is estimated that sinking with underhung tubbing would have cost 91*l.* 4*s.* 8*d.* The shaft was lined with reinforced concrete. Cement for injection of boreholes 350 tons 13 cwt., for the concrete walling 998 tons 6 cwt., and for the injection of the walling 50 tons 10 cwt. (*A. Hassam and T. T. Mawson*, Trans. Inst. M.E. lviii. p. 16.)

In porous sandstones *The François Cementation Co.* first injects separately solutions of silicate of soda and sulphate of alumina, and follows this up with cement. This process was used successfully at Hatfield Main, Thorne, etc. Two shafts were sunk successfully at Ollerton by this process.

For a more complete description of the process see paper by H. Standish Ball, *Proceedings of South Wales Institute of Engineers*, vol. xxxvi. No. 2, p. 111.

Mr. Eustace Mitton estimates the cost of sinking through the Bunter sandstone by cementation, including the installation of ferro-concrete tubbing to a depth of 200 yards for an 18-ft. shaft, at £350 per lineal yard. (*Midland Counties Institute of Engineers*, October 15, 1921.)

At two shafts recently completed at Harworth Main, where there was an indicated quantity of water of 3,000 gallons per minute, the shafts were rapidly and successfully sunk by the François process, with a total residual water in both shafts of 6 gallons per minute (see 'Harworth Sinkings,' *Colliery Guardian*, Nov. 17, 1922 ; see also p. 2578) ; while at two shafts recently completed at Ollerton Colliery, where the estimated amount of water was even greater than this, the shafts were sunk by the François process with an average of residual water of only two gallons per minute in each shaft. (See paper read by Mr. H. Eustace Mitton before the Institution of Mining Engineers (*Transactions*, vol. lxx.), November 4, 1925.)

The François cementation process was successfully employed in preference to sheet piling at Haugh Colliery, Kilsyth, Scotland, for sinking from the surface to some 6 fathoms in depth through running ground.

See also L. Souvestrie, *Annales des Mines*, 12th series ; *Colliery Guardian*, Nov. 10, 1922 ; an article in the *Iron and Coal Trades Review*, Sept. 8, 1922 ; *Kropf, Industriebau*, Oct. 15, 1922 ; 'Cementation des Grès Vosgiens,' by F. Arguillère, *Rev. Ind. Min.*, Nov. 1, 1927, p. 451. Papers by A. A. Barnes and J. R. Fox, *Inst. of Water Engineers*, June 1927.

The time required to cement a 20-yd. length of shaft in various rocks is as follows :

Bunter Sandstone . . .	16 days	Limestone . . .	18–19 days
Pennant Sandstone . . .	16 ,,	Chalk . . .	12 ,,

and the quantity of cement required per yard of 20–22 ft. shaft has been found to be :—

Pennant Sandstone . . .	15 cwt.–3 tons	Bunter Sandstone . .	5 tons–6 tons
Magnesian Limestone . .	2 tons–4 tons	Chalk	up to 4 tons.
Triassic Sandstone . . .	3 tons–6 tons		

Where silicatisation is employed, the consumption of silicate of soda is 1½ to 5 tons per linear yd., and that of sulphate of alumina about half of this.

(*Vertical Shaft Sinking*, by E. O. Forster Brown, 1927, pp. 147, 148.)

Under special conditions when very rapid setting cement is required, 'ciment fondu' has been used in place of ordinary Portland cement, and in intensely cold ground a mixture of magnesia and magnesic chloride has been used.

The Barnsley Bed was cut in the Thorne sinkings at 2,765 ft. on August 22, 1924.

The deepest working in the world at present is in the Village Deep at 7,638 ft., 2,044 ft. below sea level.

In 1924 the total depth of all shafts in mines in Great Britain coming under the C.M.R. Act was 845,000 yds, and the ratio of shaft yardage to average tons of daily output was 1 : 1·183 ; in the U.S.A. the ratio of output appears to be at least 15 times as great.

(*Vertical Shaft Sinking*, by E. O. Forster Brown, 1927, p. 372.)

Coal Cutters.

In coal-getting by longwall, props with lids are set along the working face at definite distances apart, there being 1, 2, or 3 rows, as conditions may require. As far as possible, these props are drawn as the face advances, the control of the roof being a matter of prime importance. In the U.S.A. some collieries have adopted adjustable chocks, which can be advanced by screw or hydraulic jacks. Steel props, generally in combination with corrugated steel straps or lids are used extensively in place of wood, and have been attended with a marked diminution of accidents from falls of roof, etc., at the face. Both rigid steel props and composite steel props capable of yielding to roof pressure have been used according to the character of the roof. Steel props have greatly facilitated roof control, the importance of which is generally recognised. (See *Trans. Inst. Min. Eng.*, vol. lxxvi., 1928–9, p. 236; vol. lxxvii., 1928–9, p. 158.) Steel props are generally used in combination with Intensive Mining, in which all operations at the face are carried out systematically in proper succession.

In hand kirving, the average height of a kirving is 13½ ins. in front and 1⅜ in. at back, by a depth of 3 ft., giving a volume of 1·9 cub. ft. of coal kirved out per linear foot of coal face (equal to 16 per cent. on a 4 ft. seam). In a 6-hour shift a hewer in ordinary coal will kirve a bord 5 yds. wide to a depth of 1 yd. or about 7½ sq. ft. per hour of shift. A man will kirve about 9 sq. ft. per hour's actual hewing time after the jud has been nicked in a bord; in a wall he can kirve about three-quarters as much as in a bord, and in longwall work he can kirve one and a-half times as much as in average narrow work. Allowing for his other work a hewer in Northumberland and Durham averages about 38 sq. ft. of kirving per shift.

Machine cutting gives up to about 65 per cent. more output per man employed; on the average about 10 per cent. more round coal is made by machine than by hand and a greater output of coal can be obtained from a given seam.

Coal-cutting machines for longwall work are chain-cutters, disc-cutters and bar-cutters, the former being applicable in seams where the coal is fairly hard, the cleat not too well marked, and the roof tolerably good. The disc machine makes a kirving 3½ ins. to 5½ ins. deep, the bar machine a kirving tapering from 7½ ins. in front to about 3½ ins. at the back. Machines may be air-driven, using compressed air at 35 to 65 lbs. per sq. in. at the machine, or electrically driven (direct, alternating, or tri-phase) at voltages of 250 to 450. The power consumption varies between wide limits, between 12 and 30 h.p. Compressed air coal-cutters cost 250*l.* to 300*l.*, electrically-driven coal-cutters 350*l.* to 450*l.*; a complete plant for a pit using 10 machines would cost about 10,000*l.* with the former and 11,000*l.* with the latter form. The area undercut per hour varies from 45 to 140 sq. ft., 90 sq. ft. being about an average, per hour of running time. An average shift's work may be taken as about 500 sq. ft. Air consumption 1,000 to 3,000 cub. ft. free air per sq. yd. undercut.

According to Mr. Mavor (*Trans. Inst. Min. Eng.*, vol. l., p. 641) a good compressor will compress 6 cub. ft. free air per minute to 60 lbs. per sq. in. per b.h.p. Tests showed coal cutters to use 143 to 1,146 cub. ft. free air per minute, or 620 to 3,642 cub. ft. per sq. yd., at mean pressure of 23 lbs. per sq. in. at machine and 68 lbs. at compressor.

COST.

Mr. Mavor gives average costs as follows:—

	Per shift. s. d.	Per ton. d.
Interest 5 per cent. on 450*l.*	1 9	0·21
Depreciation 12½ per cent.	4 4	0·52
Labour	33 0	4·00
Air power	23 0	2·77
Picks, oil, etc.	8 4	1·00
Repairs	12 10	1·50
Total	83 3	10·00

Gate-end loaders are coming into use. Face conveyors are largely used.*

In narrow work percussive coal-cutters are mostly used, also chain-heading machines and arc wall machines. Percussive cutters supported on a fixed column are largely in favour; they work with compressed air at 50 to 70 lbs. per sq. in., the air consumption being 100 to 300 cu. ft. of compressed air per sq. yd. undercut; different makes run at 300 to 600 blows per minute. A machine has undercut 30 sq. ft. per hour, but their usual performance is 80 to 100 sq. ft. per shift. Percussive cutters of the Ingersoll type on wheels are also used; these machines weigh 5 to 7½ cwts.; they use air at 70 to 90 lbs. pressure per sq in., with an average consumption of 100 cu. ft. of free air per min., and strike about 150 blows per min.; they will undercut 15 to 50 sq. ft. per hour of running time, or 50 to 200 sq. ft. per shift.

Chain heading machines may be driven electrically or by compressed air, using 10 to 20 h.p.; these machines can undercut about 50 sq. ft. per hour, but it is rare that 200 sq. ft. can be kirved per shift. See 'The Driving of Narrow Places,' by S. Walton-Brown (*Trans. Inst., M.E.*, vol. lxxiii, 1927, p. 506).

* See "Underground conveying and Loading of Coal by Mechanical Means," *So. & W. Yorks Coalowners Assocn. and Midland Inst. Min. Eng.*, 1929.

Arcwall machines will cut 10 to 15 places per shift in roads 4 to 5 ft. wide, the usual depth of undercut being about 6 ft.; these machines weigh about 3½ tons, and their motors develop about 40 h.p.

The Stanley header cuts roads circular in cross-section through coal, using 15 to 40 i.h.p. A road 5½ ft. in diameter can be driven through coal at the rate of 10 ft. per 8-hour shift, or six times as fast as handwork, the cost being sometimes rather less, sometimes rather more than hand labour, namely 2*s*. 6*d*. to 4*s*. per foot of advance, everything included, as against 2*s*.8*d*. by hand.

The Jeffrey Entry driver cuts, breaks down, and loads the coal into tubs.

In the U.S.A. Longwall machines with jibs 40 ft. long cut and load 350 tons per shift. A machine with a 50 ft. jib is worked by five men, and in a 6 ft. seam with a strong sandstone roof cuts and loads 200 tons per shift or 400 tons per day; a machine with a 200 ft. jib, to cut and load 1,000 tons per shift. is being built.

In connection with coal-cutters, in thin seams face conveyors are much used for bringing the coal to the gateways. There are four main types:—(1) troughs containing scraper-chains, either endless or reciprocating, (2) endless belts, (3) shallow trucks or trays hauled by ropes, (4) shaker conveyors. The Blackett conveyor is an example of the first type; the chain is 6-inch pitch and rests in a trough 12 ins. wide at the bottom, 18 ins. at the top, 9 ins. deep, made in 6 ft. lengths; it will carry up to 30 tons per hour along faces 100 yds. in length. Most of the other forms have lower capacities. and are suited to smaller outputs or shorter faces. In one case where hand-cutting and filling cost 2*s*. 4*d*. per ton (face costs only), machine cutting and hand filling cost about 1*s*. 8*d*. per ton (1*s*. 4*d*. face costs, plus 4*d*. for power, repairs, stores, depreciation), and machine cutting and conveyor filling 1*s*. 3*d*. (9*d*. and 6*d*. respectively). In most cases a considerable saving is shown, especially in stonework, but the amount varies considerably according to circumstances.

See Report of an Investigation of the Underground Conveying and Loading of Coal by Mechanical Means. *Midland Inst. Min. Eng.* (R. Olive), 1929.

On the Continent shaking trough conveyors are much used, and are also coming into use in this country. (See *Glückauf*, vol. 61, 1925, pp. 89–149, and vol. 63, 1927, p. 1449.)

Face loaders are coming into use in the U.S.A. Amongst the leading types are:

O'Toole loader—undercuts the coal so that it falls on to a belt conveyor.
Jeffrey loader—somewhat similar in principle; it has been introduced into Great Britain.
Wilson chain loader—has gathering arms combined with a conveyor.
Joy loader—is a combined digger and conveyor.
Goodman machine—somewhat similar in principle.
Myers Whalley—mechanical shovel loading into tubs.

Jeffrey Co. and others make scrapers combined with conveyors.

Wages and general costs may be taken as 50 per cent. higher in 1930 than all those here given.

The 'Hardiax' Coal Cutter.
(The Hardy Patent Pick Co., Ltd., Sheffield.)

This cutter consists essentially of a long stroke air-drill, which is fixed in position and held up to its work by means of a solid drawn steel tube provided with powerful jack-screw and

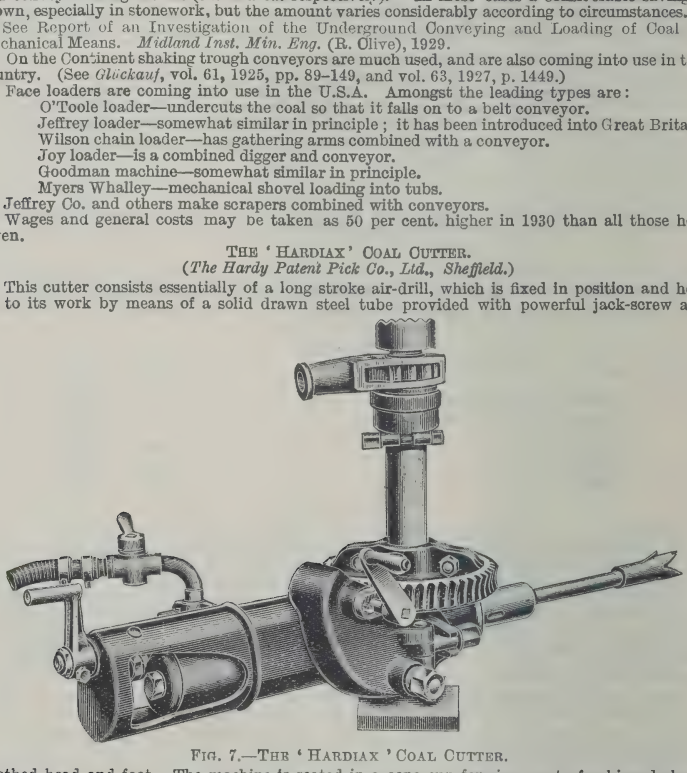

Fig. 7.—The 'Hardiax' Coal Cutter.

toothed head and foot. The machine is seated in a cone cup forming part of a hinged clamp attached loosely to the column. This clamp carries a worm, the teeth of which mesh with those

of a worm-wheel bolted rigidly on the column. By turning the worm-handle the coal cutter is caused to move around the column, whilst the forward movement into the coal is obtained by the feed screw controlled by a handle at the back of the machine. Figs. 7 and 8 give side views of the complete apparatus fixed for work at floor level. The machine may be fixed to cut at any height between floor and roof. The friction between the hinged clamp carrying the machine and the column itself is regulated to a nicety, relieving the worm of the shock of the recoil without in any way impeding the free movement of the machine right and left across the coal face.

When air is admitted to the machine the rapid and powerful blows quickly cut away the coal or other material, whilst the machine is swung right and left by the worm gear and fed forward as is necessary. An arc-shaped and continuous channel or undercut is thus speedily made, increasing in depth and width as each successive length of cutter-bar is inserted in the piston of the machine.

As soon as the desired depth is attained at the centre of the working place the operator commences to play in gradually decreasing sweeps upon the right- and left-hand sides of the arc-shaped cut, using longer cutter-bars where necessary until the undercut or channel is of uniform depth at every point, and square at the sides and corners. When pillars are taken out, or in working on a longwall face, the successive cuts break into one another, giving a continuous undercut of perfectly even depth the whole length of the coal face, whatever this may be. The cut may be any width up to, say, 20 ft. from one setting of the column. The depth of the cut is generally from 4 ft. to 6 ft. and the height 3¼ ins. to 4¼ ins. The diameter of the cutters is varied to suit different requirements.

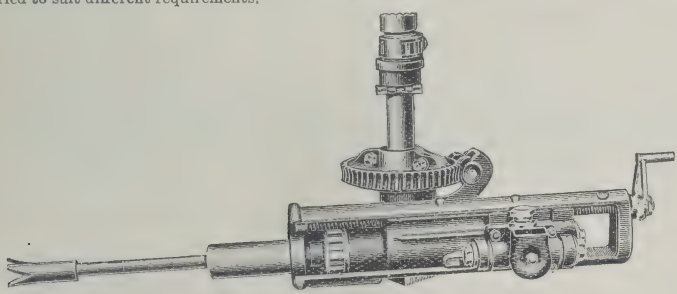

FIG. 8.—THE 'HARDIAX' COAL CUTTER.

The special constructional features of the machine are: (1) Crucible Cast Steel Cylinder. (2) Crucible Cast Steel Valve Box. (3) Crucible Cast Steel Cradle. (4) Crucible Cast Steel Gears. (5) Valve and Main Piston Hardened and Ground.

The machine is provided with a new patented piston valve action, giving great cutting power with low air consumption.

The air-pressure should, preferably, be from 40 to 60 lbs. per sq. in. or more, at which pressure the air consumption is approximately 120 cub. ft. free air per minute.

Shaft Pillars.

The 'draw' in ordinary Coal Measure strata, practically horizontal, is generally between 5° and 15° to the vertical. In Staffordshire 'draws' between 8° 45′ and 11° 10′ were observed in strata dipping 1 in 24 (W. Hay, *Trans. Inst. Min. Eng.* xxxvi. p. 47). The Final Report of the Coal Conservation Committee (Cd. 9084), 1918, p. 64, implies that the maximum angle of 'draw' to be expected is 26° 35′. In secondary strata the 'draw' is generally between 15° and 30°.

There are reasons for assuming that the angle of draw in practically horizontal strata approximates to $45° - \frac{\text{angle of repose}}{2}$.

In Westphalia (*Zeitsch. f. B. H. u. S. W.*, 1897) the draw in the Coal Measure has been found to be 15° on both rise and dip sides when the dip of the seam is $< 15°$; for dips exceeding 15°, the draw is 15° on the rise side and increases uniformly up to 35° on the dip side, reaching this value with seams dipping 35°. In the overlying clay deposits the draw is uniformly about 20°. The depth of subsidence is $kT \cos a$, where T is the thickness of the seam and a its inclination, k is a coefficient, which is 0·8 when the goaf is not stowed at all; with a well-stowed goaf, k is 0·4 when a is 0° to 10°, 0·3 when a is 10° to 35°, and 0·25 when a is 35°.

When a structure on the surface has to be protected from damage, a portion of the seam of coal or other mineral, usually spoken of as a pillar, has to be left unworked, and its position and dimensions must be calculated according to the draw. The simplest case arises when a single bed of mineral, lying horizontally, is worked out, and if the problem is to support a single point on the

surface, obviously the pillar will be circular in plan, having a radius equal to D tan b, where D is the depth of the seam below the point to be protected and b the angle of draw. In fig. 9, PS= D, the depth of the seam, and SM or SN is the radius of the protecting pillar. It follows that if a number of seams one below the other are being similarly worked out, the pillars left in the lower

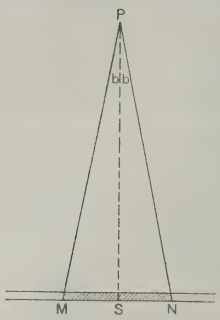

FIG. 9.

seams will be progressively larger in proportion to the depth below the surface at which the seams occur. This method may be fairly well applied as long as the dip of the seam is less than 3°.

When the seam is inclined the position becomes more complicated, and is not thoroughly understood yet. The following may be taken as a general rule: Let b_1 be the angle of draw on the

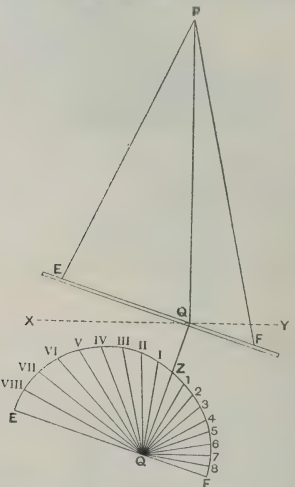

FIG. 10.

lower side of the excavation, *i.e.*, on the rise side of the pillar, and let b_u be the angle of draw on the upper side of the excavation or the dip side of the pillar, b being the normal draw when the strata are horizontal,

then

$$b_l = b + ckf(i) \text{ and } b_u = b - kf(i),$$

where i is the inclination of the seam of mineral measured in the usual way to the horizontal, c and k are coefficients, and $f(i)$ is some function of the inclination. This formula is purely empirical and should not be applied where i exceeds 30°; furthermore, $kf(i)$ can never exceed b.

Apparently $f(i)$ may be taken as sin i, k (in the coal measures) has approximately the value of 18, and c between 1·8 and 2.

Based on this formula, it is possible to calculate the dimensions of the pillar to be left in an inclined seam below a point on the surface which is to be supported, the depth of the seam below the point being, as before, D. It is easiest to calculate the dimensions of the pillar in the plane of the seam, and these can readily be projected on a horizontal plane if required.

The length (in the plane of the seam) of the pillar in the direction of full rise is given by the expression D sin b_l/cos $(b_l - i)$ and in the direction of full dip by D sin b_u/cos $(b_u + i)$, whilst the width at right angles to the dip will be D tan b on either side of the centre. Intermediate points must now be calculated as shown in fig. 10, where P is the point to be supported, Q being a point in the seam vertically beneath it. QZ is drawn in the line of strike, QE to the full rise, and QF to the full dip, the lengths of these lines being determined as above. Divide the quadrant ZQE into equal parts by radial lines set out at angles of 10° to each other, such as the lines Q I, Q II . . . Q VIII. In an inclined plane dipping at an angle of $i°$, a vertical plane making an angle of $x°$ with the horizontal will cut the inclined plane in a line having a dip of $y°$, such that tan y= sin x tan i. Thus the tangent of the inclination of the line Q I = sin 10° tan i, of the line Q II= sin 20° tan i, etc. By substituting the values of these angles of dip for i in the formula given above, it is possible to calculate the angles on the rise and dip sides respectively, and in this way the radii of the pillar in the plane of the seam can be determined, as shown in fig. 10, where D is assumed to be 500 ft., i 18°, and b 10°. The shape of the pillar thus obtained is an inconvenient one, and in practice it is best replaced by a rectangle with truncated corners just sufficiently large to include the curved area obtained by the above calculation. For approximations a circle drawn on the line of full dip may be substituted, or spirals increasing regularly from the width of the pillar on the strike to the length of the pillar on the full rise and decreasing in the other direction from the width of the pillar on the strike to the length of the pillar on the full dip.

(See ' Protection Against Damage by Subsidence,' by H. Louis, *Trans. Inst. Min. Surv.*, 1928.)

Another method, being practically that of Mr. T. A. O'Donahue,* is as follows :—If D be the depth of the seam and T its thickness, in a horizontal seam a pillar of radius R should be set out such that R = (0·19 + 0·01 T)D, all dimensions being in feet. If the seam is inclined at an angle $d°$ as above, the distance from the vertical through the point to be protected to the edge of the pillar on the rise side should be $R + \frac{2D}{3}\left(\frac{\tan d}{1 + \tan^2 d}\right)$, and on the dip side $R - \frac{D}{3}\left(\frac{\tan d}{1 + \tan^2 d}\right)$. A circular pillar should be set out with radius $R + \frac{D}{6}\left(\frac{\tan d}{1 + \tan^2 d}\right)$, the centre of the circle being at a distance $\frac{D}{2}\left(\frac{\tan d}{1 + \tan^2 d}\right)$ to the rise side of the point S. If a rectangular pillar is preferred, the square circumscribing this circle may be set out. Various other formulas have been proposed, but the two above given appear to be satisfactory.

In practice it is generally an area and not merely a point that has to be protected, the area being usually a circle, a square, or a rectangle. As a general rule this can be done in various ways. If the area is a circle or a square the radii of the pillar can easily be calculated. In other cases a number of suitable points on the periphery of the area (*e.g.*, the corners of a rectangle) should be selected and the protecting pillar for each be determined as above; the irregular figure thus obtained should be enclosed in a figure of some simple form (*e.g.*, a rectangle with truncated corners), re-entering angles being avoided. In cases like this, where the solution of the problem involves so many uncertainties, an approximate result is all that can be obtained, and a liberal margin should be allowed for safety.

Bord and Pillar working.—Pillars may be square but are mostly rectangular, sides varying from 30 to 80 yds.; 30 yds. by 40 yds. to 40 yds. by 60 yds. are usual sizes. Some engineers give areas proportional to depth; for seams 100 to 200 yds. from surface, pillars about 30 by 40 yds.; 200 yds. to 300 yds., 35 by 50 yds.; 300 to 400 yds., 40 by 60 yds.

The Coal Conservation Committee of the Ministry of Reconstruction recommends the following proportions :—

Depth from Surface.	Area of Pillar.
< 100 yds.	300 sq. yds.
100–200 ,,	500 ,,
200–300 ,,	800 ,,
300–400 ,,	1100 ,,
400–500 ,,	1400 ,,
500–600 ,,	1700 ,,

* See 'Subsidence caused by Coal-Mining,' by T. A. O'Donahue, *Trans. Inst. Min. Eng.*, vol. lxxviii, 1929, p. 91.

In *panel working* a rib 30 to 60 yds. wide is left between the districts, the latter being usually 20 to 50 acres in area. In American mines the width of rib is often determined by the expression T (5 + 0·01 D), where T is the thickness of the seam and D its depth below surface.

Welsh Stall working.—Single stalls are usually about 12 yds. wide with 12-yd. ribs, double stalls up to 18 yds. wide with 24-yd. ribs between them. In America the following method is sometimes used :—

Width of pillar $W = \frac{T\ D}{100}$, and width of stall $= \frac{D}{W}$, where T is the thickness of seam and D its depth, both in feet.

Subsidences.

(See ' Surface Subsidence caused by Mining,' by H. Louis, *Soc. Ing. Civ. France*, 1928. Also Second and Final Report of the Royal Commission on Mining Subsidence. Cmd. 2899. 1927. ' Mining Subsidence,' by Hy. Briggs, 1929.)

According to O'Donahue, the working out of a coal seam 4 ft. thick will cause a subsidence of the surface of 3 ft. if the seam be not more than 200 yds. deep, and from 12 to 18 ins. if it be 800 yds. deep. It was shown that at Monkwearmouth, working two seams 6 ft. and 4 ft. thick respectively at depths of 1,725 ft. and 1,600 ft., caused surface subsidences of 6 ft. to 6 ft. 9 ins.

At Dunkirk collieries working two seams 5 ft. and 6 ft. thick, 50 yds. apart, at a depth of 445 yds., caused a subsidence of 6·8 ft. in five years and 8·92 ft. in ten years, after which it ceased.

In Staffordshire working a 5 ft. seam at a depth of 1,626 ft. caused surface subsidences varying from 1·34 to 1·47 ft.: these reached their maximum in about 29 months.

In the Doncaster district the surface subsidence may be expected to be about 60 to 70 per cent. of the thickness of the mineral extracted. (Report on Mining and Drainage in an area around the County Borough of Doncaster. Ministry of Agriculture and Fisheries, 1928.)

Final subsidence at the surface is equal to the thickness of the seam actually worked out (*i.e.* the thickness of the seam after allowing for any stowage) less the expansion due to the breaking up of the superincumbent measures. If t is the thickness of the seam and d the depth of the seam, both in feet, and k the coefficient of expansion of the strata, the surface subsidence equals $t - kd$; in ordinary coal measures with seams of moderate thickness and at moderate depths k appears to be of the order of 0·2 per cent., so that if D is the depth of the superincumbent strata in hundreds of feet, then the subsidence equals $t - 0{\cdot}2$ D feet. The coefficient appears to increase with increasing thickness of the seam, which gives the strata more room to break, and it decreases as depth increases, probably because the weight of the overlying strata re-compresses to some extent the strata expanded by fracture, and this effect appears to be sufficiently well marked to prevent $t - kd$ ever coming down to zero, though it is not impossible that it might do so in the case of narrow seams at very great depth.

There are too few data available to give numerical expressions for the above general statements.

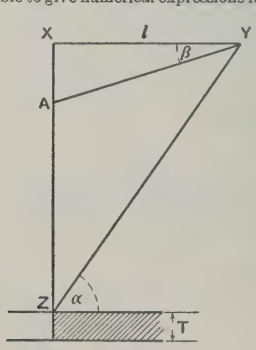

FIG. 11.

Besides the vertical subsidence over the worked-out area, a zone of draw exists over the solid coal, the breadth of which = depth of seam × tan angle of draw as given above. Let XY, fig. 11, represent the zone of draw.

Let S = XA be full vertical subsidence; l = XY be length of draw (width of zone of draw); H = depth of seam; T = thickness of seam; $\alpha°$ = angle of draw measured to the horizontal, said to be about 70° in coal measures; $\beta°$ = angle of inclination of drawn surface.

There is a horizontal displacement from Y to X, and this is a maximum in the middle of the zone of draw, becoming zero at X and Y.

Tan $\beta = \frac{S.}{l}$ l = H cot α. For seams 4ft. to 10 ft. thick, S = (0·5 to 1·0) T, when unstowed, (0·25 to 0·5) T, when hand-stowed. Maximum horizontal displacement varies from 0·05 to 0·3 T and = $\frac{Sl}{4H} = \frac{S \cot \alpha}{4}$.

(*A. H. Goldreich, 'Die Bodenbewegungen im Kohlenrevier und deren Einfluss auf die Tagesoberfläche.'* 1926.)

In the Zwickau (Saxony) district seams dipping 15°, aggregating 28 ft., worked at depths from 2,000 ft. to 3,000 ft., cause subsidence of 70 per cent. of thickness worked by goafing, 40 per cent. by hand-stowage, 10 to 5 per cent., averaging 7 per cent., by hydraulic stowage. The angle of draw by the two former methods is 80°, flatter by last-named method. In mining under densely built-over areas hydraulic stowage gives better protection against damage than leaving safety pillars. (*Goldreich, op. cit.*)

Working Costs in Getting Coal.

Working brokens is usually about 25 per cent. cheaper than working in the whole coal.

(But see 'The Driving of Narrow Places,' by S. Walter-Brown, *Trans. Inst. M.E.*, vol. lxxiii. 1923, p. 506.)

Typical examples of basis yard prices in whole coal to show relative costs:

	2 yds. wide.	3 yds. wide.
Winning headways	1*s.* 6*d.*	1*s.* 2*d.* per yard.
Holing walls	1*s.* 5*d.*	1*s.* 2*d.* ,,
Bords	1*s.* 1*d.*	0*s.* 11*d.* ,,

In brokens.—Jenkins, 3 yds. wide, 8*d.*; half-pillar walls, 3 yds. wide, 10*d.*; skirtings, 3 yds. wide, 6*d.* per yard.

Allowances for wet places ½*d.* to 1*d.* per ton; for band up to 2½ ins. thick, ½*d.* per ton, with ½*d.* additional for every further inch in thickness of band. For taking down ramble 3 ins. to 6 ins. thick, 1*d.* additional per ton, with 1*d.* additional for every further 3 ins.

Longwall.—Hewing price is usually about halfway between whole and broken tonnage price. An average hewing price may be taken to be 1*s.* 6*d.* per ton for a 3-ft. seam, the price rising or falling 1*d.* per ton for every 1 in. decrease or increase in thickness of seam.

All these prices are subject to local percentage increases.

PERCENTAGES OF ITEMS IN PRICE OF COAL AT PIT'S MOUTH.

Year	1913.	1901.	1866–96.	1700–50.
	Per cent.	Per cent.	Per cent.	Per cent.
Royalty	5·35	7·96	8·5	12·5

Hydraulic Stowage.—The best built packwall will compress down to 70 per cent. of its original height, whilst hydraulically stowed material will not compress to less than 90 per cent. Material used in Germany varies from sand to washery residues about 1½ in. cube. Cast-iron pipes 6 to 8 ins. diameter are used, often lined with hard cast-iron or porcelain. A cast-iron tube 7½ ins. in diameter ¾ in. thick will transport about 1,300,000 cub. yds. of stowage material before it is worn out. The average cost of tubes is 3*d.* per cub. yd. stowed. Average rate of stowage 25 to 30 cub. yds. per hour; some mines stow over 4,000 cub. yds. per day. The total cost of hydraulic stowage varies from 4*d.* to 1*s.* 6*d.* per ton of coals got—average appears to be under 1*s.*

In a trial run in Scotland the working costs amounted to 9*d.* per cub. yd.

(Professor R. W. Dron, *Institute of Mining Engineers*, November 1923.)

According to P. Francke (*Glückauf*, 1926, p. 1156) hand stowage produces a settlement of 40 per cent. of the thickness of the seam, including 10 per cent. settlement before stowing, and hydraulic stowage a settlement of 5 to 15 per cent., averaging 10 per cent.

A modified form intermediate between hydraulic and hand stowage is described in *Ann. Mines Belg.* vol. 28, 1927, p. 501. Pneumatic and mechanical stowage are also being used.

Colliery Consumption.

According to the Coal Conservation Committee of the Ministry of Reconstruction, 1918, colliery consumption in Britain varies from 5 to 9·43 per cent., averaging 6·8 per cent., of which 6·2 per cent. is produced by the direct combustion of coal under boilers, and the balance from outside sources. In 1923 colliery consumption amounted to 6·11 per cent. and miners' coal to 2·34 per cent. of the output, and in 1924 to 6·21 per cent. and 2·46 per cent. respectively.

The capital cost of a modern colliery may be taken at 20*s.* to 30*s.* per ton of coal got per annum.

Mining in Veins and Masses.

Methods employed in veins are:

Underhand stoping.
Overhand stoping.
Combined underhand and overhand stoping.
Rill stoping.
Shrinkage stoping or magazine mining.

Irregular deposits, wide veins, thick and steeply inclined seams may be worked by the following methods:—

Lost pillars.
Vertical slices.
Horizontal slices taken transversely.
Horizontal slices taken longitudinally.
Top slicing.
Caving.
Magazine mining.
Square set timbering.

Of these, overhand stoping is the most general, underhand stoping being only used in quite special cases, as when there is only a small quantity of payground to be taken below a given level. Overhand stoping can be used for veins of medium width, say up to 10 ft. on the average. Rill stoping is mainly employed in Western Australia. Magazine mining suits veins of any width, provided that they are not too flat, that the walls are fairly good, and that the whole of the veinstuff has to be extracted. Slicing and caving are used in wide veins and irregular masses when the value of the mineral is not great and where cheap methods of working are essential; it is largely used in the hæmatite mines of Cumberland and Lancashire. Square sets can only be used where the mineral is valuable and where large timber is abundant and cheap.

* *Third Report of Fuel Economy Committee. Brit. Assoc.*, 1920.
† Royal Commission on Coal Industry (1925).

The following classification has been drawn up by the Committee on Mining Methods of the *Amer. Inst. Min. Met. Engs.*, vol. lxxii. 1925.

- **Open cut with or without stripping**
  - Benches
  - Glory holes and milling
  - Placer mining
    - Hand sluicing
    - Dredging
    - Hydraulicing
- **Underground methods**
  - Breast stoping (tabular flat-dipping deposits or beds)
    - Continuous horizon
    - Casual pillars
    - Room-and-pillar
  - Underhand stoping (veins and large masses)
    - Glory hole and milling
    - Open stope
      - With pillars
      - With stalls
      - With square set timbering
  - Overhand stoping (steep-dipping veins or masses)
    - Open stope
      - With pillars
      - With stalls
      - With square set timbering
    - Filled stope
      - Horizontal cut and fill (flat-back)
      - Inclined cut and fill (rill)
      - Square set timbering
      - Piercing or stripping
    - Shrinkage stope
    - Sub-level stopes
  - Top slicing (wide veins or masses)
    - Continuous horizon
    - Panel slicing
    - Block slicing
    - Inclined slicing
  - Caving (large masses)
    - Sub-level caving
    - Block caving
      - Undercut from main level
      - Undercut from sub-levels
      - Back caving into chutes
      - With branch raises
- **Combined methods (large masses)**
  - Alternate shrinkage stope, and pillar
  - Pillars mined by: top slicing, sub-level caving, or block caving
  - Square set timbering: pillars mined by slicing

See 'The Working of Unstratified Mineral Deposits' by G. J. Young, 1927.

The costs of stoping vary within very wide limits, and may be illustrated by typical examples.

In Western Australia, with the contract system in force, a miner breaks 7·31 tons of ore per shift. Formerly a miner on day's pay broke only 4 tons per shift.

In eleven of the West Australian mines treating from 9,000 to 22,000 tons of ore per month with veins varying from 4–20 ft. to 6–60 ft. in width the stoping costs per ton of ore ranges from 6*s.* 4*d.* to 9*s.*, averaging 7*s.* This includes breaking ore, filling stopes, trucking, hoisting, etc. On the Rand it costs from 3*s.* 6*d.* to 5*s.* 6*d.* to stope a ton of milling ore in stopes 40 to 60 inches in height. To these figures must be added cost of compressed air, rock drill maintenance, steel sharpening, and administration underground. The first three factors amount roughly to about 1*s.* per ton, while the last would not exceed 1*d.* In some Rand mines one man can break 12 tons per shift per machine, and uses one case (50 lbs.) of blasting gelatine to break 3·5 fathoms of ground. At other mines only 7 tons are broken per man and one case of explosives is used to break 2·5 fathoms.

In Nevada at the Silver Peak Mines each miner breaks 8·6 tons of rock per shift. The total stoping cost is 5*s.* per ton. Miners here receive 16*s.* per shift.

At the Braden Copper Mines native miners break 12 tons of ore per man per day with rock drills in moderately hard rock. The total cost per ton of ore broken, including superintendence and general charges, is given as 1*s.* 9*d.*

In Utah in quartzite with a stoping width of 10 ft., square set system, small air drills, the stoping cost per ton varies from 6*s.* to 8*s.*

At Douglas Island, Alaska, the ore is a mineralised igneous rock of fair hardness, the workable portions of which vary upwards from 30 ft. in width. Wages 12*s*. Machine used 3¾ inches piston diameter. The following figures are taken over a year's working :—

COST OF BREAKING GROUND AT DOUGLAS ISLAND, ALASKA.

General Details.	Ready Bullion.	700 Ft.	Mexican.	Treadwell.
Average number of drills used	10·12	11·586	14·917	39·13
Tons ore broken	151,460	238,696	232,875	830,551
Tons waste broken	2,756	—	10,509	1,670
Tons broken, total	154,216	238,696	243,384	832,221
Total footage drilled	241,679	269,990	362,519	803,542
Tons ground broken per machine per shift :				
Stoping	47·36	42·998	41·26	—
Developing	8·65	11·323	6·58	—
Cutting out	14·30	7·334	10·34	—
Average	23·06	30·41	24·19	28·47
Footage drilled per machine per shift :				
Stoping	29·39	33·587	33·50	—
Developing	39·14	37·78	39·71	—
Cutting out	40·11	33·954	34·79	—
Average	36·12	34·37	35·7	29·41
Tons broken per foot of hole drilled :				
Stoping	1·61	1·28	1·23	—
Developing	0·22	0·19	0·165	—
Cutting out	0·31	0·33	0·30	—
Average	0·64	0·88	0·669	0·96
Costs of breaking ground per shift per machine :	£ *s*. *d*.	£ *s*. *d*.	£ *s*. *d*.	£ *s*. *d*.
Labour	1 14 0	1 8 0	1 10 0	1 9 0
Explosives	9 8	11 4	12 2	11 4
Supplies and power	1 0 0	18 2	1 0 0	1 0 0
Total	3 3 8	2 17 6	3 2 2	3 0 4
Cost per foot of hole drilled	1 10	1 8	1 9	2 0
Cost per ton of ground broken	2 10	11	2 8	2 1
Total cost of mining, including development	4 0	4 9	4 10	4 6
Percentage of total mining cost	2 9	8	2 2	1 11

In the Granite Gold Mine, B.C., on a vein of hard quartz from 8 inches to 5 feet wide dipping 35° to 50°, the stoping costs per ton are as follows :—

	s.	*d*.
Stoping by hand	14	0
„ by ¾-in. piston drills	11	6
„ by 2½-in. „ „	8	4
„ by 2-in. hammer drills	6	4

Mining costs at the Elko Prince Mine, Nevada, in 1917, stoping a 2 ft. 6 in. vertical vein of hard quartz by magazine mining, using hammer drills with 1⅛ in. cruciform steel, were as follows :—

	Per Ton of Ore $
Timbering, including ore shoots	0·5588
Blacksmith	0·0995
Stoping	0·8083
Tramming	0·2822
Hoisting	0·1956
Compressed air	0·1288
Explosives, detonators and fuse	0·4452
Repairs	0·0486
Drill steel	0·0570
Supervision, taxes, assaying, etc.	0·4987
Cost per ton	$3·1227 = 13*s*.

(*Bull. Amer. Inst. Min. Eng.*, Aug. 1918.)

Costs of stoping in 1903 in two mines on Cripple Creek, Col., in narrow veins: machinemen, $4; miners, $3 for 8 hour shift; coal, $4·60 per ton; timber, $20 per mil.

	I.	II.	
Machinemen and miners	$0·34	$0·369	
Shovellers and trammers	0·41	0·401	
Timbermen	0·23	0·215	
Total labour underground	$0·98		$0·985
Compressed air, rock drills, sharpening	0·15		0·179
Tramming, trams, etc.	0·03		0·034
Explosives	0·13		0·139
Timber	0·28		0·310
Hoisting and surface transport	0·23		0·254
Miscellaneous stores	0·04		0·291
Supervision and general expenses	0·23		
	$2·07		$2·192
	= 8s. 7½d.		= 9s. 1½d.

For detailed costs of mining operations in various West Australian mines, see pages 2594–2597.

Drilling.

Ordinarily two men can drill double-handed 25 to 33 ft. of 1-inch holes per day in limestone, 4 to 8 ft. in granite. With double hammers 10 ft. of 2-inch holes can be drilled in medium rock.

On the Rand generally one white man and five Kaffirs run two air-drills; in some cases one white man and seven Kaffirs run three drills. Eight 6-ft. holes is considered a shift's work for two machines; these holes break on an average two fathoms of ground. The cost is as follows:—

	£	s.	d.
One white man	1	5	0
Five Kaffirs		15	0
Powder for two machines		16	0
Maintenance		4	0
Total	3	0	0 per fathom.

In Chili, with native labour, contracts are let on the basis of the number of holes drilled. The rock is moderately hard.

By hand.—1,008 man-days, by single hand work, drilled 13,855 ft. at a cost of 4·1*d.* per foot. Average amount drilled per man per day 13·8 ft.

By machine.—The actual cost of drilling for one month was as follows:—164 man-days (9 hours) with two ¾-in. air drills, drilled 5,082 ft. at a cost of 1·01*d.* per foot. Average amount drilled per man-day, 31 ft.

It is well known that drilling in siliceous rocks produces a dangerous dust, recognised as the origin of Miners' Phthisis. The amount of dust suspended in the air is tested by the Kotzé konimeter; the atmosphere is considered safe if there are less than 300 dust particles per c.c. (Final Report of Miners' Phthisis Prevention Committee, Pretoria, S. Africa.)

The Safety in Mines Research Board has devised a filter bag connected by a flexible tube with the hole which is being drilled; this catches the particles of dust produced in drilling. (Paper No. 23, 1926.)

See "Silicosis and Coal Mining," by J. S. Haldane, *Inst. Min. Eng.*, Jan. 1931.

HAULAGE.

Rails.

Mine rails weigh 10 to 40 lbs. per yard. The following table shows the least weight that should be used for the given loads (weight of 1 loaded tub) and low speeds:—

Loads, in cwts.	7	10	15	20	25	30
Weight of rails per yard, lbs.	10	12	15	18	20	22
Gauge of track, in inches	15–18	15–18	16–20	18–22	20–26	20–30

For speeds above 5 miles per hour heavier rails are to be preferred.

Weight of 1 mile of single track in tons = 1·571 × weight of rail in lbs. per yard.

Sleepers 2 ft. 6 ins. to 3 ft. 6 ins., usually 3 ft. apart.

Sleepers 8 ins. to 12 ins. longer than gauge of track, 3–4 ins. deep, 6 ins. wide. A pair of fishplates and 4 bolts for 18 lb. rails, weigh 4–8 lbs., usually 5 lbs.; 100 dogspikes for same weigh about 14 lbs. Weight of fishplates, bolts and spikes is approximately 1 cwt. per ton of rails.

To bend rails to any curve, let l be length of rail, r radius of curve, both in feet, a the middle ordinate in the centre of the curve, b the quarter ordinate, midway between a and the end of the rail (both a and b in inches):—

Then

$$a = 1{\cdot}56\,\frac{l^2}{r}, \qquad b = 1{\cdot}17\,\frac{l^2}{r}.$$

Width of track ¼ in. to ⅜ in. greater than gauge of wheels.

Additional width round curves:—

Gauge of track	15	18	24	30 ins.
Additional width	¼	½	⅝	¾ in.

In going round a curve with locomotive traction or on self-acting inclines, the outer rail must be elevated; with rope haulage the inner rail may have to be elevated.

Let

e = super-elevation in feet; s = gauge of track in feet; v = velocity in feet per second; r = radius of curve in feet;

then,

$$\text{for outer rail, } e = \frac{v^2\,s}{32{\cdot}2\,r}.$$

For inner rail, the elevation depends upon whether the centrifugal force due to the velocity of running is greater or less than the inward pull on the drawbar; it will be greater at high speeds, say, exceeding 20 miles per hour, and less at low speeds; under ordinary conditions at 15 miles per hour the elevation of the inner rail should be about 2 ins.

Colliery Tubs.

Colliery tubs carry from 7 to 40 cwts. of coals.

In North country average dimensions of tub body are about 3 ft. 9 ins. × 3 ft. × 2 ft.; wheels 11 ins. diameter, axles 1¾ in. diameter.

Such a tub if made of wood will carry about 7½ cwts. of coals, if of iron about 9 cwts.; wooden tubs weigh about 55 per cent. of the load, iron tubs about 50 per cent. Tubs cost approximately 16*s.* to 17*s.* per cwt., and their upkeep is about 10*s.* per annum. Upkeep is often reckoned at 1*d.* per ton of coal. In South Wales much larger tubs, holding up to 2 tons, are used; the general tendency in other parts of the country is towards increasing the size of tubs.

Using ordinary tubs carrying about 10 cwt. of coals, it is usually reckoned that a colliery requires for its equipment about one tub per ton of coals raised per day.

In U.S.A. colliery tubs carrying 1 to 4 tons are in use; average 3-ton tub, 9 ft. 6 ins. long, 4 ft. 3 ins. wide, 1 ft. 3 ins. high.

Coefficient of friction of tubs on well-kept mine road (level), 1 per cent. to 3 per cent., average say 1·5 per cent.; with tubs badly greased on roads in bad repair may be two to three times as much. Coefficient of sliding friction (wheel spragged) is from 12 to 20 per cent.; if m be coefficient of rolling friction, m' of sliding friction, the coefficient of friction with:—

1 wheel spragged $= \frac{3m + m'}{4}$; 2 wheels spragged $= \frac{m + m'}{2}$; 3 wheels spragged $= \frac{m + 3m'}{4}$.

Additional friction in going round curve of radius r, where the gauge of the track $= s$ (both in feet) is $\frac{s}{2r}\,m'$.

Tractive effort with 18-in. wheels on good level track, 40-in. gauge, at 5 to 6 m.p.h. = 24·3 lbs. per ton with plain bearings, 12·8 lbs. with roller bearings. (*Trans. Amer. Inst. Min. Eng.*, vol. lv. p. 29.)

A wooden tub with plain bearings at speed of 1·75 m.p.h. showed coefficients of friction:—

$\frac{1}{3\cdot0}$ with poor, $\frac{1}{6\cdot5}$ with average, $\frac{1}{6\cdot8}$ with good lubrication.

Coefficient on starting from rest with average lubrication $\frac{1}{5\cdot0}$; tests with plain bearings at collieries gave $\frac{1}{6\cdot0}$ $\frac{1}{3\cdot3}$, and $\frac{1}{5\cdot5}$ respectively. A steel tub with plain bearings gave $\frac{1}{5\cdot8}$ with Climax bearings $\frac{1}{6\cdot5}$, with Skefko ball bearings $\frac{1}{13\cdot5}$; tub with Rowbotham wheels $\frac{1}{6\cdot5}$.

A 9-ft. radius curve trebles, a 12-ft. radius curve doubles, the coefficient of friction with fixed wheels; loose wheels give ⅔ of increase of fixed wheels.

Starting effort to get up to a speed of 1·75 m.p.h. = 2 to 3 times the effort required to maintain that speed with plain bearings, 1½ to 2 times with Rowbotham wheels, and 1 to 1½ times with Skefko ball bearings. (J. Wilson, *Trans. Inst. Min. Eng.*, lxiii., p. 294.)

With 'wheel' greasers the consumption of grease averages about ¼ lb. per tub per diem for ordinary collieries.

On the average a putter can put 10 tons of coal over a distance of 200 yards (level) in an 8-hour shift.

A horse does its best work when travelling at a speed in feet per second $= \frac{1}{4}h$, where h is the height of the horse in hands, and exerting a pull in lbs. of $\frac{60\,c^2}{h}$, where c is the circumference of the horse's chest in feet (*Baron*). Average pull is about 1¼ cwt.

Maximum gradient for hand putting, 17 per cent.

Maximum gradient for horse haulage, 12 per cent.

Gradient at which resistance of full tub downhill equals that of empty tub uphill:—Let W be the weight of a loaded tub, w that of an empty one, θ the inclination of the road, μ the coefficient of friction:—$\tan\theta = \frac{\mu\,(W - w)}{W + w}$ (usually $\tan\theta = 0{\cdot}015$ about).

Work done in hauling a tub of weight W up or down an incline of length $l = l\,(\mu\,W\cos\theta \pm W\sin\theta)$

Self-acting Incline.

Self-acting Incline.—Let the sets consist of n tubs each of weight w lbs., and capable of carrying W lbs. of mineral. Let the slope of the incline, assumed uniform, be $\alpha°$. Let l be the length of the rope (= length of incline) in feet, c its weight in lbs. per foot.

Let the rope be supported on rollers, the weight of which per foot of rope (= weight of one roller divided by the distance in feet between the centres of successive rollers) is r lbs. Let D be the diameter of the rollers, d of the spindle. Let μ be the coefficient of friction of the tub on rails (usually say about 0·015) and μ_1 the coefficient of friction of lubricated bearings (say 0·05 to 0·08). Let F be the frictional resistance of the drum at the head of the incline, including that of the rope coiled upon it—a figure that is always relatively small and may often be neglected. Then at any distance x feet from the starting point the full set is just able to move down the incline when:—

$$\tan\alpha = \frac{\mu n\,(W + 2w) + \mu_1\,l(c + r)\,\frac{d}{D} + F}{nW - c\,(l - 2x)}$$

By putting $x = 0$ the above expression gives the angle at which the set will just start from the top of the incline.

The time occupied in descending a distance x will be:—

$$t \text{ seconds} = \sqrt{\frac{2x\,[n\,(W + 2w) + (c + r)\,l + M]}{g\left[\sin\alpha\,(nw - cl) - \cos\alpha\left(l\,(c + r)\,\frac{d}{D}\,\mu_1 + n\,(W + 2w)\,\mu\right) - F\right]}}$$

and the velocity in feet per second v attained after travelling a distance of x feet will be:—

$$v = \sqrt{\frac{2gx\left[\sin\alpha\,(nw - cl) - \cos\alpha\left(l\,(c + r)\,\frac{d}{D}\,\mu_1 + n\,(W + 2w)\,\mu\right) - F\right]}{n\,(W + 2w) + (c + r)\,l + M}},$$

where M is the weight of the drum and its fittings and g the acceleration due to gravity.

All the above expressions are approximations, but are accurate enough for practical purposes.

When the slope is not uniform, the calculations become more complicated. If H be the total vertical fall of the incline and L its horizontal length, it is usually sufficient, with the low gradients prevailing in collieries, to use the above formulas, putting $\alpha = \tan^{-1}\frac{H}{L}$. As the denominator of the expression given above for $\tan\alpha$ increases with x, it is obvious that the incline should, whenever possible, flatten going downwards, or be concave, though not so much so as to cause the rope to rise too high above the rails. The exact shape of the curve is not very important; it may with advantage be a parabola, which may be set out by making the height h at any point distant y ft. horizontally from the foot of the incline $= \frac{y^2 H}{L^2}$. The rope will then follow the curve whenever the relations are such that $H = \frac{cl^2}{4T}$, where T is the tension of the rope.

Main-and-Tail Rope Haulage.

Main-and-Tail Rope Haulage.—Loaded tubs in sets up to 40 are hauled outbye by motors (steam-engines, compressed-air engines or electro-motors) at speeds up to 20 miles per hour, whilst the empty tubs are hauled inbye by means of the tail rope. The size of the engine depends upon the pull to be exercised when one set (nearly always the full set) is in its least favourable position. Let T be the tension in the rope in such position, made up of the weight of the set plus rope × sine of angle of inclination of the roadway, the friction of the set and of both ropes on the rollers and the pull required to accelerate the moving parts. Let O be the diameter of the steam cylinder

in inches, one of which is alone assumed to be effective at the start, let K C be the stroke of the engine in feet (K is usually $\frac{1}{6}$ to $\frac{1}{4}$), S the steam pressure in lbs. per sq. in., s the ratio of the number of teeth in the spur wheel on the drum shaft to the number of teeth in the pinion on the crankshaft, D the diameter of the drum in feet, then

$$C = \sqrt[3]{\frac{4DT}{\pi SK s}}$$

For any portion of the trip except the start (i.e. with set already in motion), both cylinders are effective, and the value as found above must be divided by $\sqrt{2}$.

These engines are usually small and run at a piston speed of 500 to 800 ft. per min.

Endless Chain and Endless Rope.

Endless Chain and Endless Rope.—Endless chain is now rarely used except on steep gradients and for short distances; it is less reliable than endless rope on long roads, requires more power and is rather more expensive to work, but admits of rather higher speeds; it may work up to 6 miles per hour; endless rope rarely exceeds 4 miles.

The following calculations apply to both methods unless otherwise stated:—

If Q be the quantity of mineral in tons to be transported per hour, W the weight in lbs. carried by one tub, V the speed of haulage in miles per hour, f the distance apart of the tubs in feet, then

$$f = 2{\cdot}36 \frac{V \cdot W}{Q}.$$

Endless chain is always over-tub haulage, endless rope may be over-tub or under-tub. In over-tub haulage the tubs must be so near together that the rope does not touch the ground between them. Let T be the least tension in the hauling rope or chain (*i.e.* between the two tubs nearest the driving pulley on the empty side), let c be the weight of the rope or chain per foot, h the height of the tub, then the distance f_1 of the tubs apart is given by

$$f_1 = \sqrt{\frac{8hT}{c}}.$$

If f is greater than f_1 empty tubs must be run on the full side.

The pull to be exerted by the engine driving the haulage is

$$\mu\left[n\ (2w + W) + 2c \cdot l\right] \cos \alpha \pm W \sin \alpha,$$

using the same notation as above, n being the number of tubs on any one side of the rope at any time, so that $n = \frac{l}{f}$; the lower sign is used when the gradient is with the full tubs, the upper one when against it. If this expression has the $-$ sign, the arrangement is self-acting.

The return wheel of an endless rope haulage is often used as a tightening pulley, being capable of sliding and pulled by a weight W.

Let the radius of the pulley, fig. 12, be R and of its spindle r.

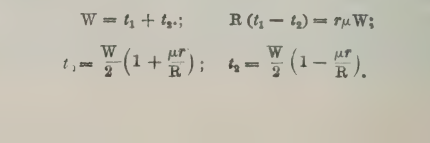

FIG. 12.

Let the coefficient of friction between the spindle and its bearing be μ.

Let the tension in the rope coming off the pulley be t_1, and in the rope leading to the pulley be t_2,

then,

$$W = t_1 + t_2; \qquad R(t_1 - t_2) = r\mu W;$$

whence

$$t_1 = \frac{W}{2}\left(1 + \frac{\mu r}{R}\right); \quad t_2 = \frac{W}{2}\left(1 - \frac{\mu r}{R}\right).$$

Horse-Power required for Haulage.

(*Trans. Inst. Min. Eng.* xv. 1897, p. 136.)

Cost of underground locomotive haulage in Westphalia in 1912, including redemption of capital outlay :—

Petrol	2·51 pence per ton-mile.
Continuous current (with conductors) . . .	2·16 „ „
Alternating „ „ „ . . .	1·58 „ „
Continuous „ (with accumulators) . . .	2·65 „ „
Compressed air	2·12 „ „

So-called fireless locomotives using superheated water, and oil or coke-fired steam locomotives are also used.

Steam Mine Locomotives.

Mine locomotives (*steam*) usually have cylinders 5 ins. to 8 ins. diameter, stroke 1½ diameters, driving wheels 20 ins. to 30 ins. diameter, wheel base 3 ft. to 6 ft., weight complete 4 to 15 tons, drawbar pull ⅓ to ⅛ weight. Boiler pressure 120 to 150 lbs. Speed with full load in miles per hour ⅛ diameter of driving wheel in inches.

When D is piston diameter, l length of stroke, d diameter of driving wheel, all in inches, and P the gauge pressure of the boiler in lbs. per sq. in. then drawbar pull = approximately, $\frac{0{\cdot}85\ P\ l\ D^2}{d}$.

Compressed Air Locomotives.

Compressed air locomotives are worked at 600 to 1,000 lbs. per sq. in. gauge pressure, charged from underground receivers, in which air is compressed to 50 to 100 lbs. higher. Pressure is reduced to about 150 lbs. per sq. in. before the air enters the cylinders. The formula above given for drawbar pull may be used, P being the pressure of air as supplied to the cylinders, writing 0·95 instead of 0·85.

Electric Locomotives.

With trolley wires, electric locomotives may use either continuous or alternating current. Weight complete is usually 7 to 15 tons, and drawbar pull $\frac{1}{6}$ to $\frac{1}{8}$, usually $\frac{1}{7}$ of weight; coefficient of adhesion, 25 to 30 per cent. 75 per cent. to 80 per cent. of electric imput is converted into tractive effort, 1 per cent. to 2 per cent. of which will move the locomotive on the level, the remainder being available for hauling load. Speed on the level usually 6 to 8 miles per hour.

With accumulators, small locomotives are used in places for secondary haulage. The B.E.V. locomotive has a battery capacity of 193 amps. at 65 volts, and can pull or push 3-ton trucks on the level. Its use is on the increase in this country.

WINDING.

In sinking pits, the excavated material is usually hoisted in steel buckets or hoppits, usually unguided, and usually single. The load is thus wholly unbalanced, geared engines are often used, and the winding speed is slow. Such buckets have capacities of 25 to 50 cubic feet, say 30 to 60 cwts., the weight of the bucket being from $\frac{1}{2}$ to $\frac{3}{4}$ of its load. For ordinary colliery work cages carrying two to twelve tubs are used, always in pairs running on wooden, rail or rope guides; in collieries in U.S.A. large skips are sometimes used instead of cages.

Skips are largely used instead of cages in metalliferous mines; when the mineral has to be crushed the fact that the skip breaks the mineral up more than does the cage is no drawback. Self-dumping skips are used on large mines, whilst underground bins and loading stations at the shaft enable the skips to be filled very quickly. Skips usually hold from 20 to 100 cubic feet, say up to about 5 tons of rock; they are made of $\frac{1}{4}$ in. to $\frac{3}{8}$ in. steel plate.

In some Illinois collieries, where the coal is to be crushed afterwards, skips about 6 ft. × 6 ft. × 12 ft. 6 ins., holding about 12 tons of coal, are used; the speed of winding is up to 1,600 ft. per min.; the average power consumption is 0·485 kw. hour per ton of coal; up to 1,000 tons of coal has been hoisted per hour from a depth of 200 yards.

On the Continent the total load lifted is about: cage 30 per cent., tubs 20 per cent., coals 50 per cent. German practice is: Let W be the weight of coals, T weight of the tubs, and Q the total weight of coals, tubs, and cage (including chains, hook, etc.); then

$$\frac{W}{T} = \frac{1}{0{\cdot}38} \text{ to } \frac{1}{0{\cdot}78}, \text{ averaging } \frac{1}{0{\cdot}56} \text{ and } \frac{W}{Q} = \frac{0{\cdot}27}{1} \text{ to } \frac{0{\cdot}44}{1}, \text{ averaging } \frac{0{\cdot}36}{1}.$$

In skip hoisting the ratio of weight of skip to that of load of mineral is 0·6 : 1 to 0·9 to 1; in hoisting in cages, weight of cage and tubs : weight of coal : : 1·5 : 1 to 1·9 : 1 (*Zsch. f. B.H. u.S.W.*, 1915, p. 285).

In Great Britain the cage usually weighs 35 to 45 per cent. of the total load, or approximately as much as the useful load of coals lifted. It is carried by bridle chains, usually six in number. Their factor of safety should be at least 10, and the size of the chains may be calculated thus:

Let d be the diameter of the chain in eighths of an inch, and W the safe working load in tons then $d = \sqrt{10W}$.

Slack adds greatly to strain on rope; according to numerous experiments, if the pull required to lift a given cage with rope taut be taken as 1, it requires a pull equal 1·5 to 1·7 with 3 ins. of slack, to 2–2·25 with 6 ins., 2·25 to 2·5 with 9 ins., and up to a pull of 3 with 12 ins.

The velocity of winding varies from 15 to 75 ft. per second; a rule given by O'Donahue is: allow a speed of 20 ft. per second for shafts up to 200 yards in depth, and add 5 ft. per second for every additional 100 yards.

Wooden guides are usually 3 ins. × 4 ins. to 4 ins. × 6 ins.; rail guides 50 to 70 lbs. per yard. Rope guides made of single strand of 7 to 15 wires each $\frac{1}{2}$ to $\frac{1}{4}$ in. diameter, stretched by weight of $1\frac{1}{2}$ to 5 tons; weight is often calculated at 1 ton for every 250 yards depth of shaft. The friction on the guides is but small; it usually amounts to about 0·025 of the total load on the rope with wooden or rail guides and 0·02 of the load with wire rope guides.

Size of Winding Engine.

To calculate the size of the winding engine the conditions of the wind must be known or assumed. The diameter of the cylinders must be such that (*a*) one cylinder is capable of starting the unbalanced load and (*b*) that the two cylinders taking steam on the full stroke shall be capable of accelerating the total load to be set in motion.

If w be the weight of a cage and fittings with the empty tubs, W the weight of minerals lifted per wind, h the depth of the shaft in feet, c the weight of the rope in lbs. per foot, v the velocity in feet per second up to which the load is to be accelerated during a lift of f feet; let P be the steam pressure in lbs. per sq. in., d the diameter of the piston in ins., S the length of the stroke in feet, D the diameter of the drum in feet, M the weight of drum, pulleys, etc., and allowing 20 per cent. to cover the friction in the shaft, of the pulleys, drum, and engine, etc., then to fulfil condition (*a*)

$$d = \sqrt{\frac{D\,(W + ch)}{0{\cdot}471\ P.S.}}.$$

To fulfil condition (*b*)

$$d = \sqrt{\frac{4\,D\left[\left\{W + c(h - f)\right\} f + (W + 2w + 1{\cdot}5\,ch + 0{\cdot}5\,M)\,\frac{v^2}{2}\right]}{3\ .\ P.f.S.}} \qquad (b)$$

The larger value of d as found by (*a*) or (*b*) should be adopted.

This formula only applies to the ordinary form of winding engine with the drum carried direct on the crankshaft and the two cranks at right angles.

On the average the total load, namely, coal, tubs, and cage, equals 2·66W; assuming a factor of safety of 10 and a rope of 100 tons steel, $c = \frac{26 \cdot 6W}{16{,}000 - 10h}$.

The diameter of a rope in inches equals approximately $0 \cdot 45 \sqrt{c}$; taking the diameter of the drum as 120 times the diameter of the rope, $D = 4 \cdot 5 \sqrt{c}$.

On these assumptions, formula (*a*) becomes

$$d = 3 \cdot 856 \sqrt{\frac{\sqrt{c}\,(W + ch)}{P}}.$$

Assuming that $S = \frac{d}{6}$, and that the diameter of the drum is 120 times the diameter of the rope, this expression takes the following form:—

$$d = 4 \cdot 59 \sqrt[3]{\frac{(W + ch)\sqrt{c}}{P}}.$$

An empirical formula which gives reasonably good results is:

$$d = 3 \sqrt{\frac{WD}{P}}.$$

Usually $S = \frac{d}{6}$ and the length of the connecting rod is $2\frac{1}{2} - 3$ S. Average piston speed 500 ft. per min., varying from 300 to 800 ft.

If the load is partially or wholly balanced, the formula must be correspondingly modified.

Once the load has been accelerated to its full speed, the steam admission is reduced by means of valve gears with variable cut-offs, and during the last part of the wind work must be absorbed so as to retard the load and bring it to rest gradually; powerful brakes are employed or the engine may be reversed as well as the brakes applied.

The weight of the rope may be balanced by:—

1. Chain counterbalance, suitable for slow winding only, and adding enormously to the weight to be accelerated.

2. Balance rope beneath the cages; this adds to the weight to be accelerated, but the chief objection is the additional strain put upon the cappings of the winding ropes. Some engineers use a balance rope heavier than the winding rope, so as to overbalance the latter, to help the engine to accelerate the load at start and to aid in retardation at the finish of the wind.

3. The conical or scroll drum. The ascending load is attached to the end of the rope which is at the small end of the drum, and the descending load to the end at the large end. Using the same notation as before, but calling r the mean radius of the drum, r_s the smaller radius, r_d the larger, Q_a the resistance due to the ascending load and Q_d the force derived from the descending load and n the total number of revolutions of the drum during the wind:—

$$r = \frac{r_s + r_d}{2} = \frac{h}{2\pi n}$$

$$r_s = r\left(1 - \frac{hc}{Q_a + Q_d + hc}\right); \qquad r_d = r\left(1 + \frac{hc}{Q_a + Q_d + hc}\right);$$

$$\frac{r_s}{r_d} = \frac{Q_a + Q_d}{Q_a + Q_d + 2hc}$$

If δ be the diameter of the rope, the width of the drum will be approximately $1 \cdot 5\, n\, \delta$.

Cylindro-conical drums, giving partial counterbalance (where most needed), are often used.

Flat ropes wound on a reel are equivalent to a spiral drum; they will counterbalance in the three main positions when

$$r_d - r_s = nt \text{ and } r = \sqrt{\frac{Q_a + Q_d + hc}{4\pi c}\, t},$$

where t is the thickness of the flat rope.

The time of banking varies considerably; it may be averaged at about 10 to 15 seconds for one deck and 25 to 45 seconds for double decks. Up to 3,000 tons may be wound in 10 hours, but 2,000 tons is not often exceeded.

The consumption of coal in winding engines varies from 0·5 to 1·5 per cent. of the weight of coals wound. Steam consumption 50 to 100 lbs. per shaft h.p. hour.

The cost of a winding engine and boilers erected varies from about 3,500*l.* to about 10,000*l.*

The cost of winding, exclusive of interest and depreciation on the winding plant, varies from about 3*s.* to 10*s.* 6*d.* per 100 tons wound.

Electric Winding Plants.

Electric winding plants are coming increasingly into favour; according to W. Mountain (*Trans. Inst. M.E.* xxxi., p. 329) the first cost of electric winders is considerably in excess of steam winders, so that interest and depreciation of the plant form serious items in the working costs. Some of the large geared electric winders in use on the Rand raise a 3-ton load from a depth of

2,500 ft., taking 2,000 e.h.p. An electric winder at a Durham pit raises 63 cwts. of coal per wind from 1,350 ft., uses 3-phase induction motor, 700 h.p., 2,900 volts; motor runs at 230 r.p.m., geared 5·45 to 1; cylindro-conical drum 10–20 ft. diam., weighing 45¾ tons; overall efficiency 51 per cent. A winder in a South Wales pit uses 2,000 volts alternating, lifts 55 cwts. from 600 ft., uses 174 kW. per wind; drum cylindro-conical, 8 ft. to 13 ft.; overall efficiency, 48·25 per cent.

ELECTRIC WINDERS ON WITWATERSRAND.

Name.	Depth in ft.	Tons (2,000 lbs.) per hour.	Weight of Mineral.	Weight of Skip.	Maximum Rope Speed.	Drum Diameter.	Winding Rope Diameter.	Tail Rope Diameter.	H.P.	System.
			lbs.	lbs.	ft. per min.	ft	in.	in.

The last-named winder (Whiting hoist) shows an overall efficiency of 77 per cent.
(J. F. Perry, *Trans. Nat. Assoc. Col. Man.*, xv. p. 299.)

At the East Geduld Mines an electric winder hoists from a depth of 3,350 ft. 1,400 lbs. per wind, 230 (short) tons per hr.; drum cylindrical 14 ft. diameter, 5 ft. between flanges, maximum speed 2,580 ft. per min.; maximum peak capacity to be 4,570 h.p.

At Aberdare colliery, N.S.W., an electric winder raises 7½ tons net per wind, 490 tons per hr. from a depth of 1,260 ft.; it is rated at 4,500–11,250 h.p. Another shaft at this colliery has an electric winder making 133 trips per hour, with a net load of 4½ tons, the maximum winding speed being 2,555 ft. per min.

An electric winder is used at Orient No. 2 mine at West Frankfort, Ill. (Chicago, Wilmington, & Franklin Coal Co.). Coal skips normally weigh 10 tons, maximum weight, 11·5 tons; coal dumped at shaft bottom from mine cars by tipplers; depth of shaft, 202 yds.; normal output, 1500 tons per hour; maximum, 2,000 tons per hour; time of wind, 16 secs.; maximum winding speed, 4,000 ft. per minute; peak load during acceleration, 8,000 h.p.; two motors, each 2,000 h.p., one placed at each end of drum shaft; motor generator set, 40 tons; fly wheel, 12 ft. diameter, equipped with two 1,800 kw., 600 volt, 600 r.p.m., d.c. generators, driven by a 2,200 h.p. induction motor 220 volts, 3-phase, 60 cycles, 600 r.p.m. At the Nemacolin Mines, Pa., the seam is 250 ft. below and the tipping platform 90 ft. above ground level; the skip carries 16 tons and the plant can wind 1,500 tons per hour; the electric winder develops 1,400 h.p., the drum being cylindro-conical.

The largest electric winder in Gt. Britain is at the Carlton Main Colliery, Grimethorpe; it raises 300 tons per hour from a depth of 2,610 ft., and can develop 7,500 h.p. at 49·6 r.p.m.: it has a 23-ton flywheel Ilgner set.

For full information on electric winders see "Electric Winders" by H. H. Broughton, 1927.

Headgears.

Headgears.—Steel-framed headgears usually range from ⅝ to 1 ton per foot of height, and cost erected 12*l.* to 18*l.* per ton; headgears composed of angles and joists only, not lattice girders, weigh ⅝ to ⅞ ton per foot of height. Wooden headgears weigh about ¼ ton per foot of height and cost 10*l.* to 12*l.* per ton. The size of the main legs of timber headgears is given approximately by the expression $A = 0{\cdot}03\ H^4\sqrt{W}$, where W is the total working load on the winding ropes in tons, H the height in feet of the headgear from the ground to the pulley centres, and A the area of the cross-section of the main leg; the area of the backstay = 0·64 A.
(R. Boyle, *Scott. Inst. Min. Stud.* 1908.)

Ferro-concrete headgears have been erected in several places and have proved quite satisfactory.

Pulleys.

Pulleys.—Usually 10 to 20 ft. in diameter, mostly of the same diameter as the drum. Pillow blocks may be carried on strong springs to diminish shock at starting.

If W be the weight of a pulley in cwts. and *d* its diameter in ft., $W = 9{\cdot}2\ (d-8)$ approximately for large colliery headgear pulleys. $W = \frac{d^2}{4}$ is a useful approximation, but is too low for pulleys under 6 ft. in diameter.

The angle of lead from the drum to the head gear pulleys should not exceed 2° on either side of the centre line; the horizontal distance between the drum and pulley centres should not exceed 150 ft., otherwise the rope is apt to surge.

The first Koepe winder, supported directly over the shaft, thus dispensing with the usual headgear and pulleys, to be erected in this country, is in operation at Plenmeller Colliery, Northumberland. The Koepe driving pulley is 11 ft. 6 ins. in diameter, driven through single reduction gearing at 200 r.p.m. by a 240 h.p., d.c. motor, fitted with Ward-Leonard control. Current is supplied by a 200 kW., 350 volt generator direct coupled to a 3-phase 50 cycle 600 volt induction motor running at 730 r.p.m. The depth of the shaft is 815 ft., and single deck cages taking 3 tubs holding altogether 48 cwts. of coal are used. The whole of the hoisting machinery is contained in a two-storied steel-framed house with corrugated iron sides and roof mounted on a tall lattice-girder framework. An overall efficiency of 60 per cent. is attained.
(*Trans. Inst. Min. Eng.*, lv. p. 170.)

Another has been erected at Murton Colliery, Co. Durham. The motor here is 400 h.p. on a 2,000 volt, 40 period current; it draws 4 tons of coals per wind from a depth of 1431 ft. in 80 secs., The coefficient of friction between rope and driving pulley has been found to be 0·407. The overall efficiency is 61 per cent. (G. Raw, *Trans. Inst. M.E.*, vol. lxxiii., 1927, p. 380.)

On the Rand, hoisting with skips costs 8*d.* to 1*s.* per ton from depth of about 1,000 ft.

ROPES* FOR HAULING AND WINDING.

Weight in lbs. of rope of circumference C inches per yard :—

Of ordinary hauling or winding wire ropes with hemp cores about	$0{\cdot}55\ C^2$.
,, ,, wire ropes with wire cores . . . . . ,,	$0{\cdot}6\ C^2$.
,, flattened strand rope	$0{\cdot}57\ C^2$.
,, locked coil rope	$0{\cdot}75\ C^2$.
,, all-steel guide ropes	$0{\cdot}65\ C^2$.
,, hemp ropes	$0{\cdot}2\ C^2$.
,, coir ,, ...	$0{\cdot}12\ C^2$.
,, aloes ,, ...	$0{\cdot}1\ C^2$.

The number of wires of diameter d in a wire rope of diameter D is approximately $0{\cdot}75\ \frac{D^2}{d^2}$.

The breaking strength in tons of ropes of circumference C inches is approximately :

Ordinary hemp rope	$0{\cdot}3\ C^2$.	Aloes fibre rope .	$0{\cdot}4\ C^2$.	Mild steel . .	$1{\cdot}75\ C^2$.
Best ,,	$0{\cdot}6\ C^2$.	Charcoal iron .	$1{\cdot}5\ C^2$.		

For ordinary ropes (with hemp cores) of	80–90 Ton wire . . .	$3{\cdot}3\ C^2$.
,, ,, ,,	90–100 ,, . . .	$3{\cdot}7\ C^2$.
,, ,, ,,	100–110 ,, . . .	$4{\cdot}0\ C^2$.
,, ,, ,,	110–120 ,, . . .	$4{\cdot}4\ C^2$.
,, ,, ,,	>120 ,, . . .	$4{\cdot}6\ C^2$.

The weight of rope in lbs. per yard which shall have a breaking strength of W tons = kW, where k has values :

For 80–90 Ton wire .	0·167	For 100–110 Ton wire .	0·138	For >120 Ton wire .	0·120
,, 90–100 ,, .	0·148	,, 110–120 ,, .	0·125		

If S is the breaking strength of the wire in tons, the strength of the rope is approximately

$$0{\cdot}04\ C^2\ S.$$

If a rope n yards in length is required to carry a load of W tons with a factor of safety of f, using wire having a breaking strength of S tons per sq. in., weight of rope in lbs. per yd. is

$$\frac{2{,}240\ f\ W}{160\ S - f n} \quad \text{or} \quad \frac{2{,}240\ k\ f\ W}{2{,}240 - k\ f\ n}.$$

If $160\ S$ is $< f n$, a stronger wire must be selected.

The British Association of Wire Rope Manufacturers has adopted the following distinctive nomenclature for the steel wire ordinarily used in rope manufacture :—

Description.	*Breaking Strain.*
Best patent steel wire	80 to 90 tons per sq. in.
Special improved patent steel wire	90 to 100 ,, ,,
Best plough steel wire	100 to 110 ,, ,,
Special improved plough steel wire	110 to 120 ,, ,,
Extra special improved plough steel wire . . .	above 120 ,, ,,

Mild steel used for special purposes has breaking strength of 26 to 80 tons per sq. in.

For wire ropes of	6	strands of	7	wires	deduct	5%	off sum of strength of wires.				
,,	6	,,	12	,,	,,	10%	,,	,,	,,	,,	
,,	6	,,	30	,,	,,	15%	,,	,,	,,	,,	
For locked coil ropes deduct . . .						5%	,,	,,	,,	,,	

* See the B.E.S.A. specifications for winding and hauling ropes.

Wire rope should never be bent round a drum or pulley whose diameter is less than 100 D, or 1,000 d; 150 D, or 1,500 d, are preferable, and the respective coefficients 120 and 1,200 are quite frequently employed. In Belgium, diameters of pulleys greater than 750 d for flat ropes, or greater than 1,000 d for round ropes, are allowed. In the Pas de Calais the following proportions of drum diameter have been adopted: for Lang's lay, greater than 68 D, for flattened strand greater than 72 D, and for lock coil, greater than 80 D.

(J. F. Perry, '*Mining Engineer*,' vol. iv., No. 34, p. 24.)

The maximum bending stress in pounds per square inch produced by bending a rope round a pulley of diameter $\triangle$ is theoretically $E\frac{d}{\triangle}$, where E is the modulus of elasticity of the wire used; it ranges from 10,000,000 to 30,000,000 lbs. Owing to the strain not acting directly at right angles to the cross section of the whole rope, it is found in practice that the mean stress is more correctly represented by the expression $\frac{3}{8}E\frac{d}{\triangle}$. According to R. W. Chapman (*Proc. Austr. Inst. Min. Eng.*, vol. iii., No. 3, April 1908), if a is the angle of pitch of the wires in a strand and b of the strands in a rope, the bending stress is $E\frac{d}{\triangle}\cos^2 a \cos^2 b$.

If s be the mean bending stress as above, T the breaking strength in lbs. per sq. in., m the factor of safety (ratio of total breaking load to total working load), W the total load to be carried, and A the total cross-section of steel in the rope, $A = \frac{mW}{T - s}$.

For ordinary winding ropes $A = 0{\cdot}6\ D^2$ approximately.

Factor of safety for haulages, from 5 to 6, for winding ropes 8 to 10.

Coefficients of friction of wire rope :—

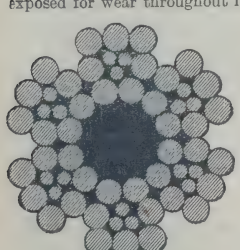
Dry rope on a grooved iron drum . .	0·120	Greased rope on a wood filled sheave	0·140
Wet " " " " . .	0·070	Dry rope on rubber or leather filling	0·495
Greased " " " . .	0·70	Wet " " " " .	0·400
Dry rope on a wood filled sheave . .	0·235	Greased " " " " .	0·205
Wet " " " " . .	0·170		

According to G. Raw (*Trans. Inst. Min. Eng.*, iv., p. 180) the coefficient of friction of a slightly oiled flattened strand rope upon an elm-filled sheave, fibres on end, is between 0·3 and 0·35.

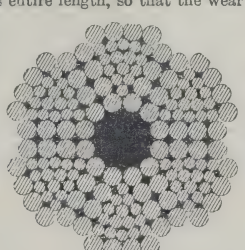
The resistance to bending of a rope under tension T lbs. round a pulley of radius r ft. $= 1{\cdot}26 + 0{\cdot}002276\frac{T}{r}$ (*Weisbach*). The maximum admissible stress in a medium wire rope may be taken as averaging 5,000 times the weight of 1 foot of the rope.

Flattened Strand Ropes.

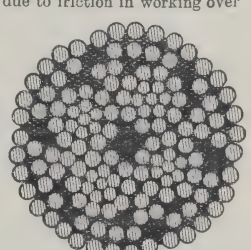
Flattened strand ropes are constructed of strands each of which has a flattened surface exposed for wear throughout its entire length, so that the wear due to friction in working over



No. 48 K.
Haulage Rope.



No. 49 K.
Winding Rope.



No. 163.
Flexible Crane Rope (Non-rotating).

pulleys is distributed over a larger number of wires than is the case with ordinary round stranded ropes. In the latter the wear is very severe on the crown wires of each strand, which are consequently, considerably reduced in sectional area before any appreciable wear has taken place in the adjoining wires. The smooth surface of flattened strand ropes materially reduces wear and tear on drums and pulleys; owing to the wear being so light on the ropes, it is not necessary to have so large a margin between the working load and the breaking strain as in ropes of ordinary make. Being more compact, they contain a larger metallic area than ordinary ropes, and therefore a flattened strand rope is of smaller size than an ordinary rope of equal breaking

strain, and is not so liable to be forced out of shape by the crushing stress it has to sustain. When required, flattened strand ropes are made non-spinning for winding and sinking purposes. They are very suitable as balance ropes, as, being absolutely dead, they can be used with or without pulleys in the sump.

Flattened strand haulage ropes splice more effectively than ordinary ropes, as the core is slightly smaller than the strands, and there is consequently less risk of the splice drawing. This construction is of special utility in ropes used for power transmission purposes, aerial ropeways, etc., where an efficient splice is essential. The greater surface of flattened strand ropes increases the holding power of grips or clips used in haulage work. For use on cranes and lifts, these smaller ropes possess special advantages, as the construction gives greater strength than the ordinary make without increase in size or loss of flexibility. Non-rotating ropes of special formation are in great demand for crane work, particularly for cranes used in the erection of large buildings, and on quays and shipping wharves, as any tendency of the rope to spin is entirely obviated.

NOTE.—The figures given above are calculated on flattened strand ropes, having six strands with hemp main core, see No. 495, p. 2607. (*Wrights' Ropes Ltd., Birmingham.*)

Locked Coil Ropes.

Locked coil ropes are in many cases advantageous where heavy loads have to be raised from great depths. Strength for strength, they are of less diameter than ordinary ropes, and consequently admit of corresponding reduction in width of drum, thus minimising lateral friction on drums and pulleys. They are absolutely free from any tendency to rotate, and are therefore of special utility in sinking operations and for winding in shafts where there is not much clearance, as the possibility of collision between the cages is obviated. Frictional wear on guides is also very much reduced by the use of locked coil ropes in winding. They are of longer duration than any other form of rope, as owing to their smooth surface the external wear is evenly distributed over the periphery of the rope, and internal friction, which is so marked a feature of ordinary ropes, is reduced to a minimum. In the event of any wire being broken in use, it is held in position and does not, as in an ordinary rope, unravel and lay across the adjacent wires, causing other fractures in working over drums and pulleys. The tendency to internal corrosion is less in locked coil ropes than in any other type of rope, as during the process of manufacture the successive annular layers of wires of which the ropes are composed are coated with a special

WRIGHTS' LOCKED COIL ROPES

for Aerial Ropeways, Cableways, Colliery Winding, Guide Ropes, etc., "immensely strong, non-rotating, perfectly balanced and smooth running in operation."

WRIGHTS' TRICOR-KEYSTONE ROPES

for Transporters, Haulage, Winding, Dredger Ladder Lines, etc., "the rope of ropes for arduous conditions—strong, resists frictional wear and cannot be crushed."

rust and acid-proof lubricant, which cannot be worn off during work owing to the protection afforded by the interlocking wires of the outer cover. In consequence of the wear on these ropes being so light, they may be worked with a lower margin of safety than is the case with ordinary ropes, as with the latter, in estimating factor of safety required, provision has to be made for the rapid wear which takes place.

As guide ropes, the advantages of the locked coil construction may be readily understood when it is borne in mind that, in the event of a rod breaking in the ordinary twisted guide rope, it would strand out from the rope, and be caught by the cage gland with disastrous results; in a locked coil rope the broken rod would be securely held in position.

Locked coil ropes are eminently desirable as standing ropes for aerial ropeways, as their smooth surface affords very easy running for the wheels of the carrier; consequently less haulage power is required and wear and tear considerably reduced.

'Rust-Resisting' Steel Ropes.

(Wrights' Ropes Ltd., Birmingham.)

These ropes are constructed from steel wires treated by a special rust-proofing process which gives them immunity from corrosive influences. The protective constituent is actually part of the structure of the steel itself and does not affect in the slightest degree its physical characteristics. The ropes have been installed in some of the leading collieries in the country and are stated to be working with complete success.

'Tru-Lay' Ropes.

'Tru-lay' ropes have the individual wires in each strand and the individual strands of the rope pre-formed into their proper shape before they are laid up, with the result that the rope has no tendency to open or to untwist, and that it can be cut without needing previous binding. Such ropes can be well secured in the 'Tru-loc' attachment, made of mild steel, which is cold-swaged on to the rope. ('Tru-lay Wire Ropes and Tru-loc Fittings,' by A. T. Adam, *Trans. Inst. Min. Eng.*, vol. lxxvi, 1928, p. 77.)

Damping Dynamic Stresses in Mine Winding Ropes.

Investigation has shown that dynamic shocks have a marked influence on the life of steel winding ropes, and has led to the design of apparatus for the continuous control of the stresses in the ropes.

The elements of the shock-damping buffer are springs and pistons moving in hydraulic cylinders; the buffer (Koepe system) is preferably interposed at the lower end of the rope, as shown in fig. 14.

The buffer is shown in fig. 15. The main bar (*b*) passes through the roof of the cage (*a*), and is connected to the piston-rod (*c*) by a bolt (*d*). The buffer itself consists of the piston (*f*), the spring (*g*), and the cylinder (*e*), and is suspended by the two trunnions (*h*), the chains (*k*), and the headpiece (*l*). The dynamic effect of the brake depends on the throttle valves (*m*) (of which there are four), through which the fluid (glycerine) contained in the cylinder is forced as the cylinder is displaced. A feather (*i*) prevents the piston from turning. An expansion space (n) is provided above the main space (*e*) of the cylinder, and connected to it by a hole (*o*). This space (*n*), which is filled only partly with glycerine, serves to accommodate the expansion of the glycerine through heat and its varying displacement by the piston-rod.

From fig. 14 it will be seen that when the lower cage is stopped at the bottom of the pit the heaviest shocks come when the portion L1 of the winding rope is above the upper cage. Some of the shocks are taken up by the natural elasticity of the rope, but if L1 is only short it cannot reduce them very much. In the first pit in which the brake was applied the dimensions of the piston and of the spring were so calculated that the effect of the damping apparatus was equivalent to that of a wire rope 400 ft. long. As the length L1 was about 200 ft., the total elasticity was tripled by the arrangement. This holds for a new rope; old ropes have not the same elasticity as new ones, and with them the relative effect of the damping apparatus is therefore much greater. The first buffers were installed in 1924 at the Hannover pit (Germany), and have since been in continuous service. The springs were designed for a normal load of 21·5 tons

which compresses them by about 6 ins. They may be compressed for 3 ins. more with a load up to 32 tons. The total height of the spring is 24 ins., and its section is 1·4 in. by 2·6 ins. There are about 12 coils in each spring.

The practical value of the buffers can be seen from the records of a winding rope. At the Hannover pit 140 wires had broken in a rope without a buffer in two years, and the rope had to be

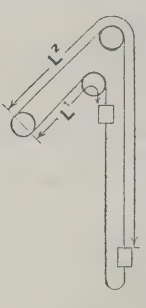

FIG. 14.

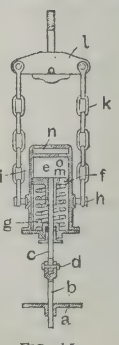

FIG. 15.

removed after this time, but after the buffers had been fitted, only 20 wires were broken in two years of use; moreover, the breaks in the wires of the rope without buffers were concentrated at certain points, but were regularly distributed in the rope with buffers. The use of this rope has been permitted up to four years, so that its life is at least doubled. Another advantage is that the renewal of the rope, which causes delays, is required less frequently.

(*Times Engineering Supplement*, *Oct.* 1928.)

STEEL WIRE ROPES FOR OIL-WELL DRILLING.

Wire ropes are largely employed in drilling oil-wells, particularly where the American system of drilling is in use, which is known as the Californian Cable Rig. This system uses a drilling line for manipulating the tools, a casing line for manipulating the casing, and a sand line for cleaning out the wells. The two former are generally 6 × 19 construction, and the latter 6 × 7.

The Russian or Galician system employs jointed rods in place of drilling lines, but wire ropes are used for cleaning out the wells and for manipulating the casing and the string of tools. The sand, pump, or bailing lines are usually 6 × 7 construction, and the other ropes, which run up to 1½ ins. diameter, are 6 × 19, 6 × 24, or 6 × 30.

Oil-well drilling, being exceptionally severe, calls for ropes of high quality.

Galvanized ropes are sometimes advisable on account of the corrosive action of the water in the wells.

It is a matter of general practice to have the drilling ropes left-hand lay.

Electrical Cables for Collieries.

See MINES AND QUARRIES FORM NO. 11, MINES DEPT. (*April* 1921).*

PUMPS AND PUMPING.

Cornish pumps from 4 ft. to 12 ft. stroke, 6 ins. to 30 ins. diameter, 12 to 16 strokes per min.; piston speeds vary from 60 to 120 ft. per min. A rule sometimes adopted is that speed in feet per second $= \sqrt{l}$, where l is the length of stroke in feet. Ram pumps work at speeds of 100 to 200 ft. per minute.

If n be number of complete strokes (i.e. up and down strokes) per min., and d the diameter of the ram or bucket, the theoretical discharge G in gallons per min. is given by $G = 0{\cdot}034d^2\ n.l$. The actual discharge is less than this by the slip, which ranges from 3 per cent. to 30 per cent.

* Printed and published by H.M. Stationery Office. Price 1*s.* net; 1*s.* 2*d.* post free.

in extreme cases. In practice it is usually between 10 per cent. and 15 per cent. It must be deducted from the theoretical discharge to get the actual discharge. Maximum velocity of water in rising main 200 to 300 ft. per min., rarely exceeds 100 ft. in small pumps; maximum velocity in windbore, 40 ft. per min.

Pressure at bottom of rising main = pressure due to static head + pressure required to overcome resistance of pipe.

If v be the velocity of discharge in feet per second, H the vertical head in feet, L the length in feet of the pipe, D its diameter in inches, and **P** the total pressure at bottom of rising main, then,

$$P = 0{\cdot}341\, D^2 \left(H + 0{\cdot}024 \left(\frac{L}{12D}\right)^4 \frac{v^2}{2g}\right).$$

The pressure in the steam cylinder must be capable of overcoming this pressure, allowing for the mechanical efficiency of the engine (say 0·66).

The content of a pipe in gallons of water = $0{\cdot}034\, D^2L$.

The thickness of a pipe can be calculated thus :—

Thickness in inches = 0·000125 P.D. + 0·5.

Thickness of pump-barrel = $0{\cdot}5 + \frac{P.D.}{2{,}000}$, where P is pressure in lbs. per sq. in.

Weight of pipe in lbs. = $2{\cdot}5\ L\ (D^2 - d^2)$, where D and d are external and internal diameters. The flange = weight of 1 ft. of pipe.

Horse-power in the water lifted = $\frac{g\ H}{3{,}300}$, where g is the actual delivery in gallons per min.

The '**duty**' of a Cornish pumping engine is the number of millions of pounds of water lifted one foot high by the consumption of 112 lbs. of coal (before 1856 of one bushel = 94 lbs., and in America of 100 lbs. of coal) under the boilers. To convert duty into lbs. of coal burnt per h.p. in the water, divide 222 by the duty. It is always theoretical discharge that is taken in calculating duty. Cornish engines have worked with as little as 1·5 lb. coal per h.p.; 2·5 to 3 lbs. is a usual figure.

For double-acting pumps the formula for discharge previously given becomes

$$G = 0{\cdot}068\ d^2 n.l.$$

If A be the area of the piston, n number of strokes per minute, S length of stroke, b the height of the water barometer, l the length of the windbore, a its area, h the vertical height of the suction lift, g the acceleration of gravity,

$$a > 0{\cdot}0055\ \frac{An^2\,Sl}{g(b-h)}$$ for single-acting pumps, and $> 0{\cdot}00275\ \frac{An^2\,Sl}{g(b-h)}$ for double-acting pumps,

or the piston will rise faster than the water can follow it, and hammering will result.

The air-vessel should have a volume = 4 times that of barrel for single-acting, and 1·6 times for double-acting pumps. (*Weisbach.*)

Centrifugal Pumps.

Let u be peripheral velocity of impeller in ft. per sec.

r radius of the impeller in feet.

n number of revolutions per second.

d depth of openings in impeller in feet.

i number of impellers in series.

h height of total lift in feet.

then

$u = 2\,n\,\pi\,r$. Velocity of radial water discharge from impeller = K u, where K is a coefficient between 0·1 and 0·3, averaging 0·2. Quantity of water discharged per second = $K\,u\,2\,\pi\,r\,d = 4\,K\,n\,\pi^2\,r^2\,d$ cub. ft. $h = c\,i\,\frac{u^2}{2g}$, where c is a coefficient that varies considerably, but is mostly between 0·75 and 1.

Mechanical efficiency (m) is between 0·5 and 0·8, usually about 0·7.

Hence h.p. required $= \frac{8\ K\ c\ \pi^4\ n^3\ r^4\ i\ d}{8{\cdot}8\ m\ g}$, or, taking average values, h.p. = about $\frac{2}{3}\ n^3\ r^4\ i\ d$.

Direct coupled motor-driven centrifugal pumps to pump 1,500 gallons p.m. to a height of 1,000 ft. have been found to have an overall efficiency of 71·6 per cent.; electrically driven ram pumps would have a similar efficiency of 80 per cent. *(Prest & Leggat.)*

(See also p. 1266).

VENTILATION.

Mine Gases and Ventilation.

Normal air contains 79 vols. nitrogen, 21 vols. oxygen, carbonic acid 0·06 to 0·11 per cent. With 17·0 vols. of oxygen a candle is extinguished, but breathing is still possible; with 15·2 vols. of oxygen breathing becomes more difficult; with 10 vols. of oxygen, very difficult; and with 5 or 6 vols. practically impossible. Prussian rule for volume of air in mines is 70 cubic feet per min. per man underground, reckoning each horse as four men; it must never amount to less than 53 cubic feet per ton of daily output.

Approximately in Great Britain 5·8 tons of air pass through coal mines per ton of coal raised.

The blood in a man's body is capable of absorbing about one pint (about 20 per cent. of its volume) of either oxygen or carbonic oxide when saturated. If it be half saturated with carbonic oxide, unconsciousness sets in, and with higher proportions death follows. In air containing 0·1 per cent. of carbonic oxide the blood would become half saturated in about an hour in the case of a man at rest, and in about half an hour in the case of a man taking exercise. Anything above 0·15 per cent. of carbonic oxide must be considered dangerous; 0·16 per cent. will cause slight distress to mice in an hour, 0·2 per cent. distress in 8 minutes, 0·3 per cent. distress in 4 minutes, 0·45 per cent. distress in 2 minutes and collapse in 4 minutes, 0·57 per cent. distress in 1 minute, collapse in 6½ minutes, and death in 12½ minutes. With canaries 0·09 per cent. causes distress in one hour, 0·15 per cent. distress in 3 minutes, fall from perch in 18 minutes, 0·2 per cent. distress in 1½ minutes, fall from perch in 5 minutes, and 0·3 per cent. fall from perch in 2½ minutes.

Fire-damp.—Fire-damp consists essentially (up to 95 per cent. or more) of marsh gas or methane, CH_4, the remainder consisting of nitrogen and carbonic acid; hydrogen and some of the higher hydrocarbons have also been found in some samples. Haller and Moureu have found helium with traces of neon (0·003–0·05 per cent.), and argon with traces of krypton and xenon (0·003–0·04 per cent.) in fire-damp. A mixture of air and marsh gas will explode if the mixture contains between 5 and 15 per cent. of marsh gas by volume. The maximum of explosive violence is attained with 9 to 10 per cent. of marsh gas. The igniting point is between 650° and 750° C., and there is always a perceptible 'lag' or delay in the ignition, the amount of which depends upon the temperature. According to Taffanel and Le Floch, mixtures containing only 3 per cent. of marsh gas will ignite at 680° C. and as much as 30 per cent. at 875°. In a mixture of 6·5 per cent. of marsh gas with air, the quantity of gas burnt per second varies from 0·00075 per cent. at 535° C. to 0·05 per cent. at 640° C. According to H. Le Chatelier the igniting point of acetylene is 450° C., hydrogen 550° C., methane and carbonic oxide 650° C. The velocity of propagation of ignition of methane ranges from 0·03 m. per sec. with 6 per cent. of methane to a maximum of 0·61 m. per sec. with 12 per cent., and falls again to 0·1 m. per sec. with 16 per cent. of methane in air. The velocity of the explosive wave in a mixture of methane with pure oxygen is 2,500 m. per sec. Marsh gas has been given off in quantities up to 4,500 cubic feet per ton of coal wrought, and has been shown to exist in coal under pressures up to 40 atmospheres. It is on record that in one mine as much as four million cubic feet of fire-damp has been given off in 24 hours.

Experiments on the ignition of mixtures of methane and air by electric sparks have been recorded by Dr. Thornton (*Trans. Inst. Min. Eng.*, xliv. p. 145, and xlvi. p. 112); the most inflammable mixture is one containing about 7 per cent. of methane. With sparks between copper poles the least continuous current capable of igniting a 9 per cent. mixture was found to be:—

50	100	240	480 volts.
4·0	0·9	0·175	0·05 amps.

With iron poles slightly greater currents are required. With alternating currents of low periodicity, the current required is far greater, ranging from 3 times at 50 volts to 12½ times at 500 volts. The higher the frequency, the larger the current required for ignition.

It has been shown that mixtures of methane and air can be ignited by the impact of siliceous rocks on each other. (Safety in Mines Research Board, Paper No. 46.)

Principles of Ventilation.

(See 'The Ventilation of Mines,' by Hy. Briggs, 1928.)

The difference of pressure producing ventilating currents in mines is measured by the water-gauge; a column of 1 in. of water corresponds to about 66 ft. of air at 60° F and 30 ins. of barometric pressure. The theoretical velocity of air due to such pressure is given by the expression

$v = 66\sqrt{h}$, where v is the velocity in feet per second and h the water-gauge in inches. If the friction in the airways of a mine is taken into account, according to Murgue—

$$h = K\frac{l\,p\,v^2}{a} \text{ or } h = K\frac{l\,p\,Q^2}{a^3}$$

where l is the length of the air passage, p its perimeter, a its area, all in feet, and Q the quantity of air in cubic feet per second. Values of coefficient K: for drifts, bricked and arched, K = 0·000,0012; in ordinary rock, untimbered, K = 0·000,0034; timbered in the usual way, dimensions taken inside timbers, K = 0·000,0057. If the quantities and velocities be given in thousands of feet per minute, these coefficients become 0·00033, 0·00094 and 0·00156 respectively; some engineers use Mr. Fairley's coefficient, which is 0·002. The critical velocity of air flowing in circular pipes $= \frac{18}{D}$ feet per min., where D is the diameter of the pipe in feet.

The work required to move a quantity Q of air under a water-gauge of h inches = 5·2 hQ foot-pounds.

Mr. J. T. Storrow has found that the quantity of air flowing through material under 0·25 in. in size at a slow rate varies directly with the pressure and not with the square root.

(*Trans. Inst. Min. Eng.*, lv. 313.)

The loss by scaling through pack walls, etc., would therefore, for the same difference in pressure, be greater than in an open airway.

Measurement of flow of air. — In a pipe circular in section a velocity equal to the mean flow is at 0·15 of radius from the wall of the pipe. In a mine drift the mean of two measurements halfway between roof and floor and one-sixth of the width of the airway from either side will approximate to the mean velocity of the air in the drift. The mean velocity is between 0·7 and 0·85 of the maximum velocity at the centre of the drift, averaging 0·78.

With the ordinary plain Pitot tube, if v be the velocity of airflow in feet per second and h the water-gauge in inches, $v = 66\sqrt{h}$; with the double Pitot tube (one branch facing the other pointing in the direction of the flow) $v = 56{\cdot}5\sqrt{h}$.

If the pressure of air on either side of a regulator or other diaphragm with an aperture of a square feet be determined by water-gauge, and the difference of gauge pressure be d inches, the quantity of air flowing is $40\,a\sqrt{d}$ cubic feet.

Natural Ventilation and Furnace Ventilation.

Natural Ventilation and Furnace Ventilation.—If there be two shafts, the mean temperature of the air in each of which is respectively T and t (in degrees Fahrenheit), the water-gauge due to this difference of temperature will be $\frac{H}{66}\left(\frac{T-t}{459+T}\right)$, where H is the depth of the pit in feet, assuming that the temperature of the atmosphere is 60° and the pressure 30 ins., under which conditions a cubic foot of air weighs 0·0765 lb.; under any barometric pressure of β inches and temperature $t°$ Fahrenheit, the weight of a cubic foot of air is $\frac{1{\cdot}326\,\beta}{459+t}$, by means of which formula the necessary correction can be applied. The number of heat units required to produce the above water gauge will be $\frac{1{\cdot}326\ Q\ \beta\ (T-t)}{459+t} \times 0{\cdot}2375 = \frac{0{\cdot}315\ Q\ \beta\ (T-t)}{459+t}$ heat units per second.

The grate area is often taken $= \frac{34}{\sqrt{H}} \times \frac{5{\cdot}2\,hQ}{550}$ sq. ft.

In practice, to pass 300,000 cubic feet of air per min. with a 2-in. water-gauge about one ton of coal is burnt per hour.

Fan Ventilation.

Centrifugal Fan.—If u be the peripheral velocity of the fan blades in feet per second, the theoretical water-gauge produced $= \frac{u^2}{68g} = \frac{u^2}{2180}$.

The manometrical efficiency of a fan ranges from about 0·45 for an open-running fan up to about 0·9 for a good modern enclosed fan.

The volumetric efficiency under given conditions is the volume of air actually passed by the fan divided by the volume of the fan × number of revolutions.

The mechanical efficiency is the horse-power required to drive the fan (or of the fan and fan-engine, as the case may be) divided by the horse-power in the quantity of air moved $= \frac{5{\cdot}2\,hQ}{550}$. It varies from about 45 to about 75 per cent. in different types of fans.

The equivalent orifice of a mine $o = 0{\cdot}4\,\frac{q}{\sqrt{h}}$, where q represents the quantity of air in

thousands of feet per minute, and o the area in sq. ft. The equivalent orifice of British mines is usually between 20 and 30 sq. ft.

If H be the initial water-gauge of a given fan (maximum water-gauge, produced on exhausting out of a closed vessel), the equivalent orifice of a fan, working on a mine with equivalent orifice o, should be $= o\sqrt{\frac{h}{H-h}}$. The inlet area of a fan should be about 20 per cent. greater than its equivalent orifice. The equivalent orifice of a fan should be about three times that of the mine on which it works. The velocity at which air enters the fan orifice should be between 1,000 and 1,500 ft. per min. If k be the manometric efficiency of any fan, according to Murgue—

$$u = \sqrt{\frac{g\,68\,h}{k}}.$$

To find the horse-power of a motor or engine required to drive a fan under average mine conditions, multiply the number of cubic feet of air by the water-gauge and divide this product by 4,500. Example: If a fan is delivering 100,000 cub. ft. of air at 2-in. water-gauge, what should be the horse-power of the motor or engine required to drive it?

$$\text{H.P.} = \frac{100{,}000 \times 2}{4{,}500} = 44{\cdot}4.$$

(*Machinery.*)

The Steart fan is an air-screw or propeller fan which is stated to give a very high efficiency and to be readily adaptable to the changing conditions of a colliery. See *Journ. Chem. Met. and Min. Soc. So. Afr.*, vol. xxiv., 1923, p. 31; *Trans. Inst. Min. Eng.*, vol. lxviii., 1924–5, p. 310.

The average consumption of brattice cloth in U.S.A. is 1,697 sq. yds. per 100 tons of coal raised. (*Report on Brattice Cloth, U.S.A. Bureau of Mines.*)

Regulators.

Regulators.—If A be the area in sq. ft. of a regulator which is required to produce as much resistance to the flow of air as a roadway of length l, perimeter p, both in feet, a area in sq. ft., K = Murgue's coefficient of friction as above when the quantity of air is expressed in thousands of cubic feet per minute and the pressure in inches of water-gauge, then $A = 0{\cdot}4\sqrt{\frac{a^3}{K\,p\,l}}$. The regulator should be placed behind the last man in the split.

Safety Lamps.

Until recently it was held that a lamp gauze should be of wire $\frac{1}{70}$ in. diameter and contain 28 meshes to the linear in. (784 meshes per sq. in.); recent researches by the Miners' Lamps Committee have resulted in recommending wire $\frac{1}{100}$ in. diameter with 20 meshes to the linear in. (400 meshes per sq. in.).

See 'Mine Lighting,' by J. W. Whitaker, 1928.

Table showing Cost in pence per 1,000 Lamps of one average Candle-power Hour, with different Oils.

Oil.	Marsaut.	Donald.	Mueseler.	Davy.	'Geordie.'	Clanny.	Scotch Davy.	Deflector.
No. 1	11½	22	14½	18	16	11½	17½	11½
No. 2	19½	33¾	32	19	—	—	—	—
No. 3	25½	43	43½	26½	—	—	—	—
No. 4	35	56	59½	42½	—	—	—	—
No. 5	45½	73	75¾	43¾	—	—	—	—

The oils used were as follows :—

Oil.	Specific Gravity.	Composition, per Cent.		Cost per Gallon.
		Mineral.	Vegetable.	s. d.
No. 1	0·820	100	0	0 9
No. 2	0·841	70	30	1 6
No. 3	0·844	50	50	1 9
No. 4	0·865	30	70	2 3
No. 5	0·889	0	100	2 9

Lamps burning benzine of sp. gr. 0·765, costing 1*s.* per gallon, gave the following results :—

	Candle-power.		Cost in pence per 1,000 lamps of one average c.p. hour.
	At Beginning.	At End.	
Wolf	0·99	0·94	16½
Protector . . .	0·72	0·66	25½

Gas Caps.

Gas caps are shown in an ordinary safety lamp with the flame turned down so as just not to show any white light, when introduced into an atmosphere containing small amounts of marsh gas or methane, approximately as follows :—

2 % of marsh gas. Cap ¼ in., just visible except at extreme tip.
3 % „ „ „ ½ in., fully formed.
4 % „ „ „ ¾ in., well defined.
4½% of marsh gas. Cap 1½ in., well defined.
5 % „ „ „ 2½ ins. „ „
5½% „ „ „ 4 ins. „ „
6 % „ „ „ fills the safety lamp.

Gas-testing lamps burning alcohol will show clearly as little as 0·2 per cent. of marsh gas.

Coal Dust.

Coal-dust.—Three ounces of coal-dust per cubic yard of gallery space is sufficient to produce an explosive mixture; excess of coal-dust prevents neither the initiation nor the propagation of an explosion. Coal-dust giving less than 12 per cent. of volatile matter is practically incapable of initiating an explosion. At least 50 per cent. of inert stone-dust is required to prevent the initiation of an explosion. If less than 75 per cent. of the dust passes the 200 sieve it is difficult to initiate an explosion. (*Abstracted from the Lievin experiments.*)

The temperature of ignition of coal-dust is about 1,000°C. Mixed with air and introduced into a heated vessel the temperature may be as low as 590°; there is very little lag. (*Taffanel and Le Floch.*)

The General Regulations provide that in all coal mines except anthracite mines and except mines of which the floor, roof, and sides of the road are naturally wet throughout, every road or part of a road shall be treated with incombustible dust in such a manner as to ensure that the dust on the floor, roof, and sides throughout shall never contain more than 50 per cent. of combustible matter, or else they shall be treated with water in such a manner that the dust is always combined with 30 per cent. (by weight) of water. It is provided that the percentage of incombustible dust required by this regulation may be reduced by an amount equivalent to the percentage of water present. The incombustible dust shall contain not less than 50 per cent. of material capable when dry of passing through a sieve with 200 meshes per linear inch. If more than 50 per cent. of dust is used, the percentage of fine material in such dust may be reduced proportionately, but shall not fall below 25 per cent. Representative tests must be made by the management at intervals of not less than one month, and the results posted at the pit head. The method in which the tests are to be made is fully prescribed by the Statutory Orders.

Rescue Apparatus.

There are three main types of rescue apparatus :—

(1) The supply of oxygen is maintained by means of compressed oxygen carried in steel cylinders.

(2) The supply of oxygen is obtained from liquid air.

(3) Oxygen is chemically generated from peroxides, usually sodium-potassium peroxide.

In (1) and (2) the expired carbonic acid is absorbed, usually by caustic soda, in (3) the reagent that evolves the oxygen also absorbs the carbonic acid.

Particulars of some forms are as follows :—

Apparatus.	Weight.	Oxygen Capacity.
	Lbs.	Cubic Feet.
Pneumatogen (Type II.)	14½	5·8
Draeger	36–39	8·9
Shamrock	36	9·7
Fleuss	31	8·0
Weg	About 30	5·3
Proto	37	8·5
Meco	39½	8·5
Salvus	16	3·0
Aerolith	22	?
Aerophor	30	?

It is estimated that 120 cubic inches of oxygen per min. is ample for the severest exercise; a man at rest requires about 15 cubic inches, and climbing hills 90 cubic inches per min. The Aerolith uses liquid air containing about two parts of oxygen to one of nitrogen; it is stated that one gallon is sufficient for three hours' work.

The Aerophor holds 10 lbs. of liquid air, equal to about 125 cubic feet.

The following has been found to be a man's average consumption of oxygen per minute, gas dry, at N.T.P.

Rate of doing Work.	Breathing.			
	Air.		Oxygen.	
	Litres.	Cub. in.	Litres.	Cub. in.
At rest	0·36	22	0·32	19·5
3,000 ft.-lbs. per min.	1·12	68·3	0·97	59·2
6,000 " "	1·74	106·2	1·54	95
9,000 " "	2·33	142·2	2·16	131·8

The most economical rate of walking when travelling a flat road and wearing a rescue apparatus—*i.e.* the rate at which a maximum distance can be covered for a given supply of oxygen—is about 2½ miles per hour.

('*Second Report of the Mine Rescue Research Committee of the Department of Scientific and Industrial Research.*')

When the wet-bulb temperature is much above 80°F., a man cannot remain long at work; he can stand a wet-bulb temperature of 120°F. for about five minutes. (*J. S. Haldane.*)

To Detect Carbon Monoxide in the Air.—A Technical Paper (No. 11) of the United States Bureau of Mines suggests the following simple test capable of detecting as little as 0·03 per cent. of carbon monoxide in the air. One or two drops of blood from a pricked finger are diluted with water until this assumes a buff-yellow colour. Some of this discoloured water is placed in two 100 cubic centimetre test tubes, and one of the tubes is to be taken into the mine, where one-half is to be poured away at the place where the air is to be tested, the mine air taking the place of the water poured away. The tube is then to be corked, taken to the surface, and to be shaken for about ten minutes. If the air in the test tube contains CO, the pink colour of the liquid will indicate its presence on comparing the tube with the other test tube filled with the normal fluid. More recently the 'Hoolamite' detector has been used extensively. This consists of iodine pentoxide dissolved in fuming sulphuric acid, the changes of colour in which indicate the amount of carbonic oxide present; it is said to be able to detect 0·07 per cent. A carbonic-oxide recorder has also been developed, which works by recording the rise in temperature in 'Hopcalite.' This consists of a catalyst combined with oxide of manganese which oxidises carbonic oxide to carbonic acid; the heat developed by this reaction is a measure of the amount of carbonic oxide oxidised. (See 'Devices for Detecting Dangerous Gases in Mine Air,' by J. T. Ryan. '*Trans. Amer. Inst. Min. Met. Eng.*' vol. lxxv. p. 599.) Mr. Ivon Graham has shown that carbon monoxide is a normal constituent of the air of coal mines over 1,500 ft. deep, being produced by the slow oxidation of carbonaceous material at the coal face, in the roads, and in the goaf; it is usually under 0·005 per cent., but in a few cases 0·012 per cent. has been found.

('*Trans. Inst. Min. Eng.*,' Vol. lix., 1920, p. 222.)

Spontaneous Combustion.

Work in the Doncaster Coal Owners' Laboratory has shown that the liability of a coal to spontaneous combustion in the goaf depends, other things being equal, upon its capacity for absorbing oxygen. It appears that a coal, 100 grammes of which, ground to 200 mesh, absorbs less

than 200 c.c. in 96 hours at 30°C., is only liable to gob fires when the working conditions especially favour the latter. Coals liable to fire absorb over 300 c.c. in the same time. Presence of pyrites especially when finely divided, increases the liability to spontaneous combustion.

Fire Extinction.

Investigations have been made recently into the scientific side of the mud-jet method of fire extinction in colliery workings, and it has been decided that the material of the mud, some of which should be of a lime and some of a clay character, should consist of sifted earth of 5 mm. mesh, boiler ash, dust from the cleaning of blast-furnace gas, and even combustible material, such as the refuse of coal washing, can be added to make up bulk without any risk should nothing more suitable be at hand. In the majority of instances the mud tank can be so placed as to operate by gravity, but steam or compressed air pressure can be used. It has been found that if a tank is placed at a height of, say, 15 yards, it will force the mud a horizontal distance of 150 yards, even allowing for fairly sharp bends in the conducting pipes.

Electric Signalling in Coal Mines.

A circular issued by the Home Office points out that while there is no difficulty in constructing bells and relays that will comply with the requirements laid down—i.e. which will not 'spark'—most of those in ordinary use in coal mines do not comply with the provision of General Regulation 132; and it states that in mines to which this regulation applies steps must be taken without delay to bring into compliance with the regulation any existing installations which do not already comply, while no new apparatus must be installed except such as does strictly comply. The fact is emphasised in the report that with the usual type of bell and magnitude of battery at present employed, nearly every break-flash that occurs when the bare signal wires are separated would ignite a mixture of firedamp and air containing between 7·5 and 9·5 per cent. of methane, were such a mixture to surround the wires at the time.

Relays, although not requiring for their action so great a battery power as bells, have owing to their higher inductance a lower 'igniting-current' at which the break-flash on the signal wires becomes dangerous. At the present time, with few exceptions, the battery power used on relays is in excess of that sufficient to give a dangerous break-flash at the signal wires. The commonest kinds of relays are dangerous when used with a battery of more than four wet Leclanché cells, or with any current in excess of the current given by such a battery.

The report shows in detail how the bare wire system of electrical signalling as commonly employed can be rendered quite secure from any danger of the ignition of inflammable gases by the break-flash at the signal wires or at the contacts of the signalling instruments.

In order to secure a safe bare-wire signalling system it is necessary in the first place that the battery power employed on any one circuit should be limited, and, in the second place, that the signalling instrument, whether bell or relay, should comply with certain requirements set out in the report.

The maximum pressure allowed by the General Regulation (No. 134 (a)) for a signalling circuit is 25 volts, and from the point of view of safety a pressure of 25 volts is not excessive, provided that, as is usual, wet Leclanché cells (quart size) are employed.

Systems in which the battery used consists of dry primary cells or secondary cells, or in which continuous or alternating current generators are employed, can be rendered safe if, in addition to the use of anti-sparking devices, sufficient non-inductive resistances are permanently installed in the circuit.

Both bells and relays should have flame-tight covers (preferably locked), and should be so constructed and maintained that when included in a circuit with a battery at 25 volts the break-flash produced, when bare signal wires are separated after giving a signal, is incapable of igniting an 8 per cent. methane air mixture.

ORE DRESSING AND COAL WASHING.

(For details see 'The Dressing of Minerals,' by Henry Louis, from which the following is mainly abstracted.)

The operations included under the head of dressing comprise all the operations between the extraction of the crude mineral from the mine and rendering it merchantable, thus forming a link between the operations of the miner and the metallurgist. By common consent, gold milling is generally looked upon as a dressing operation, though it is doubtful whether cyanidation should also be included.

The various operations consist of:—
Hand picking or sorting.
Comminution (coarse breaking or crushing and fine breaking or grinding).
Sizing (preliminary or rough sizing and final or fine sizing).
Classifying.

Separation by differences of specific gravity, magnetism, electric conductivity, or surface tension.

Usually a more or less complicated series of operations is required, especially in the case of complex ores, and these are usually indicated by means of flow sheets.

Let the weight of feed in any concentration process be A and its assay a per cent., the weight and assay of concentrates be B and b and of tails C and c respectively, then the

$$\text{Enrichment ratio} = \frac{b}{a} = \frac{\%\ \text{Recovery}}{\%\ \text{Concentration}}.$$

$$\%\ \text{Concentration} = \frac{100\text{B}}{\text{A}} = \frac{100(a-c)}{b-c}.$$

$$\%\ \text{Recovery} = \frac{100b(a-c)}{a(b-c)} = \frac{\text{B}100b}{\text{A}a}. \quad \text{A} = \frac{\text{B}(b-c)}{a-c}.$$

$$\%\ \text{Efficiency of concentration} = 100\,\frac{\text{B}}{\text{A}}\left(\frac{b}{a} - \frac{100-b}{100-a}\right) = 100\,\frac{a-c}{b-c}\left(\frac{b}{a} - \frac{100-b}{100-a}\right) =$$

$$100\,\frac{\%\ \text{Recovery} - \%\ \text{Concentration}}{\%\ \text{Waste in feed}}.$$

(*R. T. Hancock.*)

Sorting is performed either on floors or on picking belts or tables. An ordinary coal picking belt may be of iron plates 4 ft. wide, 50 to 100 ft. long, travelling at 40 to 65 ft. per minute. Pickers stand on both sides, 7 ft. to 15 ft. apart; each picker can treat 1–3 tons of coals per hour.

Power required to drive, 2½ to 5 h.p. Upkeep, about 50*l.* per annum.

Rubber-covered canvas belts about 32 ins. wide are also used, and will carry 25 to 50 tons per hour at speeds of 30 to 60 ft. per minute.

Circular tables are 3 to 4 ft. wide, 10 ft. to 18 ft. in diameter, revolving with a peripheral speed of 40 to 60 ft. per minute, and can deal with 30 to 70 tons of mineral per hour.

Comminution.—Rough breaking is done by jaw breakers, either reciprocating like those of the Blake, Dodge, etc., type, or gyrating like the Gates type. The former have been built to take pieces up to 5 ft. by 7 ft., requiring 300 h.p. to drive, and breaking 300 tons per hour. Smaller breakers usually break 1 ton per hour for a consumption of 2–3 h.p. The gyrating crusher is better suited to very large outputs, but cannot take such large pieces, and appears to be rather more economical of power.

Fine Crushing.—Rolls are used for medium and fine crushing. Let r be the radius of the particle to be broken and d the radius of the particles in the crushed product (both considered as spheres); the minimum radius of the roll should be $> 25\,(r-d)$.

For fine crushing to about ⅛-in. mesh the following table shows the general practice :—

Rolls.		Revs. per minute.	Horse-power required.	Cwts. crushed per hour.
Diam.	Face.			
10½ ins.	10½ ins.	130	3	25
12½ ,,	10½ ,,	110	4½	45
16 ,,	10½ ,,	90	6½	65
21 ,,	10½ ,,	75	9½	100
27 ,,	11 ,,	45	12½	145
37 ,,	12 ,,	45	16	200

The peripheral speed should be greater the finer the product required; for grinding to 40 mesh the speed should be 1,000 ft. per minute.

In large plants three or four sets of rolls are placed in series so as gradually to reduce the ore to the desired size. At Mount Morgan, such a plant consisted of eight sets of rolls in two series of four, thus :—

26 ins. diam.,	15 ins. face,	set	⅜	in. apart,	112 revs. per min.
26 ,,	15 ,,	,,	5/16	,, ,,	,,
30 ,,	16 ,,	,,	¼	,, ,,	,,
30 ,,	16 ,,	,,		in contact	,,

The total power consumption was 100 h.p. and the crushing capacity 125 tons per 24 hours crushed to 20 mesh (0·025 in.); the wear on the steel roll-shells was 0·108 lb. of steel per ton of ore crushed.

Stamps.—The ordinary gravitation stamp is used more largely for gold milling than for other purposes, but also for crushing tinstone, etc. The complete stamp consists of the head, shoe, stem and tappet, the weight of which may be up to 1,500 lbs. The relative weights are about 30, 17, 40, 13. It is lifted by a cam forming the involute of a circle; if h be the lift of the stamp, r the radius of the pitch circle of the involute, and α the angular motion of the cam during the lift, $h = \frac{\pi r \alpha}{180}$. The speed is usually about 90 drops per minute.

If n be the number of drops per minute, h the drop in inches, s the number of stamps, and w the weight of a stamp in pounds, the power required is approximately $\frac{nhsw}{300{,}000}$. (For a more exact formula see 'A Handbook of Gold Milling,' by H. Louis.) The average crushing capacity is 2–8 tons per 24 hours for a 1,000 lb. stamp. The Husband atmospheric stamp with two heads requires 35 h.p. to work it, and can crush 40 tons of hard tinstone per 24 hours down to 0·048 in. In modern practice on the Rand stamps are used as preliminary crushers, breaking to ½ to 1 in. and are much heavier than above given.

Steam stamps are used mainly for crushing the copper-bearing rocks of the Lake Superior Mines, down to about ¼-in. mesh. One such stamp will crush 10 tons per hour, the efficiency being about 1·75 tons per i.h.p. per 24 hours.

Ball mills have been made both for dry and wet crushing. The Krupp mill is a dry-crushing mill; the No. 5 size, which is largely used, is 86 ins. diameter by 46 ins. length, makes 20–25 r.p.m., weighs 182 cwts., and a set of balls weighs 18 cwts. At Mount Morgan these mills require 13 h.p. and crush 22·7 tons per 24 hours to 20 mesh (0·025 in.). The balls wear at the rate of 0·725 lb. and the hunch plates at the rate of 0·681 lb. per ton of ore crushed.

Wet crushing ball mills are 60 ins. to 80 ins. in diameter and about 40 ins. long. A charge of balls for such a mill weighs about 2 tons; it is run at 25 to 30 r.p.m., takes from 25 to 35 h.p. to drive it, and will crush 25 to 100 tons down to 0·02 mesh per 24 hours; the water consumption is about 65 gallons per minute.

The tube mill is also used wet or dry, and is in effect an elongated ball mill, 3 ft. to 5 ft. in diameter and 13 ft. to 26 ft. long. A tube mill 4 ft. in diameter, 16 ft. 6 ins. long, crushed in Western Australia 38 tons of sand per 24 hours, 95 per cent. of the product being finer than 100 mesh, requiring 30 h.p. to drive it. Such mills are lined with silex, chilled iron, or hard steel bars, and are usually charged with flints. According to Mr. Davidson, the best number of r.p.m. $= 200 \div \sqrt{d}$, where d is the internal diameter in inches; the weight of flints in pounds should be $N \div 44$, where N is the internal capacity of the mill in cubic feet. Western Australian practice corresponds nearly to $N \div 60$.

The Marathon mill uses rods in place of balls; a mill 3 ft. diam., 7 ft. long, charged with 7,000 lbs. of rods ½ in. to 2 in. diam., running at 30 r.p.m., crushed 18 tons per hour with a consumption of 12·5 h.p., using 42 U.S.A. gallons of water per minute. The feed was below ¼-in. mesh and the product was ground to $\frac{1}{64}$-in. mesh, 14 per cent. being below $\frac{1}{200}$-in. mesh. The wear of the liner plates was 0·14 lb. and of the rods 0·4 lb. per ton of feed.

(*Trans. Amer. Inst. Min. Eng.*, lv., p. 678; lvii., p. 355.)

The Hardinge tube mill has the form of two cones base to base. An 8 ft. Hardinge mill requires 50 h.p. to drive it, and requires about 10 h.p. hours per ton crushed to about 48 mesh.

An 8 ft. × 22 ft. mill crushed 200–250 tons per 24 hrs. using about 56 h.p., with a charge of 5 tons of Danish pebbles wearing at the rate of 2·16 lbs. per ton of feed; with steel balls instead of pebbles 360–400 tons were crushed per 24 hours.

(*Trans. Amer. Inst. Min. Eng.*, lv., p. 678.)

The Marcy mill is a short mill (5–6 ft.) with perforated diaphragm at the discharge end, from 2 ins. to 48 mesh. An 8 ft. by 6 ft. mill driven by a 225 h.p. motor crushes 550 tons per 24 hours at 24 r.p.m., carrying 30,000 lbs. chrome steel balls.

(*C. T. Van Winkle, Trans. Amer. Inst. Min. Eng.*, vol. lix. (1918), p. 227.)

The Huntingdon mill is made in three sizes, 3 ft. 6 ins., 5 ft. and 6 ft. diam.; No. 2 is most used; it weighs about 5 tons; consumes 12 h.p.; makes 60–70 r.p.m., and will crush about 10 tons per 24 hours to about 15 mesh.

The Arrastra is 10 to 20 ft. in diameter, has usually four dragstones, 6–8 cwts. in weight At 6 to 12 r.p.m. a charge of 1 to 3 tons is ground in 2–3 hours.

The Chilian mill has 2–3 rollers, 4 to 6 ft. in diameter, takes up to 75 h.p., and crushes up to 150 tons per 24 hours.

Sizing.—For coarse screening fixed grizzlies or 'jigging' screens are used. For medium and fine screening mostly trommels, 8 ft. to 2 ft. in diameter by 12 ft. to 3 ft. long; the peripheral velocity is usually 50 to 200 ft. per minute. The slopes may vary from 5° to 14°, averaging about 7°. A set of seven trommels, 3 ft. diam., 5 ft. long, will size about 7 tons of ordinary crushed material per hour, and require up to 5 h.p. to drive it. For the finest work, vibrating screens are used. Wedge wire is often used for the screening surface.

Classification.—This term applies to the separation into groups of equal falling particles The terminal velocity of a particle falling freely in water is approximately $V = 2{\cdot}6\sqrt{D(S-1)}$; where V is the velocity in metres per second, D the diameter in metres of the screen mesh through which the particle just passes, and S the density of the mineral.

The above is Rittinger's law, based on Newton's, according to which resistance $\propto$ velocity^2 R. J. Lunnon has recently shown that this law is not strictly true. (See 'Fluid Resistance to Moving Spheres,' *Proc. Roy. Soc. A.*, vol. cx., 1926, and vol. cxviii., 1928; also *Trans. Inst. Min. Eng.*, vol. lxxvii., 1929, p. 66.)

When V is less than 0·5 to 1, according to the substance, the law on which these formulas are based (friction $\propto$ velocity^2 and viscosity negligible) no longer holds good. The particles fall more slowly and obey Stokes's law:

$$v \text{ (in c.m.)} = \frac{g}{18} d^2 \frac{S - s}{\mu}.$$

The minimum radius of a particle that obeys Rittinger's law of terminal velocity is

$$\sqrt{\frac{9\mu^2}{2g(S-1)}} \text{ cm.}$$

where μ is the viscosity (0·0115) and g the acceleration of gravity (981), both in C.G.S. units, S is the specific gravity of the particle, s of the fluid, and d diameter of particle in cm.

Hence log radius in cm. $= \bar{3}{\cdot}92764 - \frac{1}{2}\log(s-1)$.

The following table is calculated from the above formula:—

Sp. gr.	Radius in mm.	Sp. gr.	Radius in mm.	Sp. gr.	Radius in mm.	Sp. gr.	Radius in mm.	Sp. gr.	Radius in mm.	Sp. gr.	Radius in mm.
1·2	0·1528	1·6	0·1004	2·0	0·08465	2·4	0·07567	3·5	0·06237	5·5	0·05128
1·3	0·1265	1·7	0·09534	2·1	0·08201	2·5	0·07395	4·0	0·05870	6·0	0·04950
1·4	0·1149	1·8	0·09118	2·2	0·07966	2·6	0·07238	4·5	0·05575		
1·5	0·1071	1·9	0·08768	2·3	0·07757	3·0	0·06719	5·0	0·05333		

Spitzkasten: the first box should be 2 ft. wide for 10 cub. ft. pulp per minute, or 1–2 cwts. of solid matter; boxes may increase in geometrical progression with factor of 1·5; length of first box about 6 ft., increasing by 3 ft. for each successive box.

Trough classifiers 10 to 20 ft. long, 1 ft. wide at narrow end, will treat 100 tons per 24 hours, with 100 cub. ft. of water per ton of crushed material.

Jigs.—The following represents the general modern practice:—

Diam. of particle .	0·25	0·50	0·75	1·00	1·25	1·50	1·75	2·00 ins.
Length of stroke .	0·4	1·2	1·55	1·8	2·0	2·15	2·3	2·4 ,,
No. of strokes per min.	200	160	145	130	125	125	125	125

CONTINENTAL JIGGING PRACTICE ON ORDINARY LEAD-ZINC ORES.

Three to five compartment jigs; screen surface 20″ × 31·5″.

Size of Particles.	Length of Stroke.	Strokes per Min.	Water per Cwt. treated.	Capacity per Sq. Ft. of Screen Area per Hour.
Inch.	Inch.		Gallons.	Cwt.
0·04	0·2	280	90	0·6
0·046 to 0·06	0·25	280	73	0·9
0·06 to 0·08	0·35	260	60	1·2
0·08 to 0·11	0·50	240	55	1·6
0·11 to 0·16	0·60	220	52	1·8
0·16 to 0·22	0·80	200	50	1·9
0·22 to 0·32	1·00	180	46	2·0
0·32 to 0·43	1·20	160	45	2·1
0·43 to 0·63	1·25	140	54	2·2
0·63 to 0·87	1·60	140	58	3·7
0·87 to 1·25	2·00	140	61	4·3

Jig screens of steel wire are liable to rapid corrosion when pyritic ores are being treated; wire drawn from Ambrac (Cu75Ni20Zn5) has been recommended in such cases.

Round buddle; diam. 18 ft. to 25 ft.; makes 5–10 r.p.m. Capacity 1½–3 cub. ft. per min. carrying 28 to 56 lbs. material; time of filling 3–10 hours.

Slime table; diam. 15 ft. to 25 ft.; ½–1 r.p.m. Pulp 1½–3 cub. ft. per min., carrying 4 to 7 lbs. per cub. ft. Clear water 1½–3 cub. ft. per min. Power required ½–1½ h.

Frue vanner; belt surface 4 ft. by 12 ft.; fall 3 ins. to 6 ins.; travel 6 ft. per min.; strokes 200 per min. Capacity 0·25 to 0·5 cub. ft. pulp per min.; 5 to 8 tons material per 24 hours. Clear water ½ of pulp. Power required ½ h.p.

Lühring vanner; belt surface 3 ft. 6 ins. by 12 ft.; travel 8–12 ft. per min.; 160–180 strokes per min. Capacity 2½–7½ tons per 24 hours; clear water 1–2 cub. ft. per min. Power required ⅓–½ h.p.

Wilfley table; 16 ft. long, 6 ft. wide, tapering to 3 ft. Will take particles up to ⅛ in. 240 strokes per min., ¾ in. long. Capacity 25 to 50 tons per 24 hours. Clear water 1 to 3 cub. ft. per min. Power required 1 h.p.

Coal Cleaning.*

Coal as it comes from the mine is first screened, usually over a 2 ins. to 2¾ ins. screen; the oversize drops on to picking belts, where shale, dirty coal, etc., are picked out. The undersize is taken to a washery, especially when it is required for coke-making. A jigging screen with ¾-in. holes will screen about 1 ton per hour for each 0·75 sq. ft. of screening surface.

Coal is sometimes dry-cleaned in the Purdee spiral separator, in which it is allowed to slide down a spiral track, the clean coal falling over the outer edge, whilst the shale, etc., remains on the track.

When the separation of the clean coal from the accompanying shaly matter is easy, or when the products are not required in the highest possible state of purity, a simple form of washer may be used. Such is, e.g., the Elliott trough washer, capable of treating 5 to 10 tons of small coal per hour with a water consumption of 1,750 gallons per ton of coal washed. The Blackett washer is similar in principle, but the fixed trough with the moving dam-plates is replaced by a revolving drum within which is a spiral baffle-plate; it will treat 10 tons of small coal per hour, requiring 3,000 gallons of water in circulation per ton of coal washed. The Robinson washer works on the principle of a spitzkasten, with upward flow of water and a revolving stirrer; it can treat 15 to 20 tons of small coal per hour.

The purity of the washed coal is usually determined by floating it in solutions of known specific gravity; coal that floats in solutions of sp. gr. 1·35 to 1·45 is generally considered clean coal. The washing characteristics of a coal are best determined by constructing a washability curve or Henry curve. (See *Colliery Engineering*, 1925, p. 341.) The washability of coals is

* See 'The Preparation of Coal for the Market,' by H. Louis, 1928.

generally determined by plotting the proportions of the whole which float in solutions of definite specific gravities against the ash contents of these fractions as a curve, from the shape of which much valuable information as to the washing properties of the coal may be obtained.

Most plants for complete washing make use of jigs (bashes or boxes), and the coarser refuse is sometimes crushed and re-washed. See flow-sheet No. 1., p. 2629.

The Coppée Washery is typical of the more usual form of plant. The unwashed coal, say under 2 ins. to 3 ins., is sized before washing. The washing is carried out in two types of boxes, viz.: (*a*) Small coal felspar boxes, which treat all the coal below ½ in.; (*b*) nut coal type of box, which treats the various sizes below 3 ins. and above ½ in. These sizes vary according to local conditions and the requirements of the market. The nut washers are 8 ft. deep, and the sieves are 5 ft. long and 3 ft. to 5 ft. wide, each washer treating 2·5 to 3·5 tons per hour per foot of width of screen. The more important data affecting the operations of nut washers are shown in the following table:—

Size of Nuts.	Depth of Layer of Shale on Sieve.	Length of Stroke.	No. of Strokes per Minute.	Mesh of Sieve.
½ in. to ½ in.	2½ ins.	2½ ins.	80	$\frac{1}{10}$ in.
½ " " 1 "	3 "	3 "	75	$\frac{1}{8}$ "
1 " " 2 ins.	3½ "	3½ "	70	¼ "
2 ins. " 3½ "	4¼ "	4¾ "	65	$\frac{5}{16}$ "
3½ " " 5 "	5½ "	6¾ "	60	$\frac{3}{10}$ "

The Felspar Washer is built in two compartments, each 4 ft. long, making a total length of 8 ft. by 2 ft. 6 ins. wide, the box being 5 ft. deep; such a washer can wash 7 to 10 tons of small coal per hour up to ½ in. in size. The following are the leading data:—

	1st Compartment.	2nd Compartment.
Thickness of layer of feldspar	2½ ins.	2½ ins.
" " shale	$\frac{3}{10}$ in.	$\frac{2}{16}$ in.
Size of pieces of felspar	$\frac{8}{10}$ in. to 1 in.	$\frac{6}{10}$ in. to $\frac{8}{10}$ in.
Length of stroke	0·55 in.	0·47 in.
No. of strokes per minute	165	165
Mesh of screen	0·55 in.	0·47 in.

A plant to wash 100 tons per hour, 50 per cent. on nut washers and 50 per cent. on felspar washers, would require four of the former, 4 ft. wide, and six of the latter. Such a plant would require in circulation about 135,000 gallons of water, and make-up water amounting to between 2,800 and 3,500 gallons per hour.

When the refuse from the nut washers contains sufficient intergrown coal to be worth treating, it is crushed, generally in a disintegrator, and the crushed material is re-washed on felspar washers.

A coal washery may require from 1·5 to 3·5 h.p. for each ton of unwashed coal treated per hour, varying with (*a*) the total output of the washery (a large washery requiring a relatively smaller h.p. per ton); (*b*) the quantity of interstratified coal, and whether the larger size is crushed and washed together with the smaller size, or whether the smaller size only is re-washed; (*c*) the type and capacity of draining and storage bunkers, and whether apparatus is installed for mixing the various products.

Messrs. Simon-Carves, Limited, build washeries on the so-called Baum principle, in which washing precedes classification. The slack below about 2 ins. is delivered to a bash having an area of about 0·8 sq. ft. per ton per hour; the washed coal then passes to a screen of about ⅜-in. mesh; the over-size is clean coal, and the under-size goes to a second bash having an area of about 1 sq. ft. per ton of coal per hour, the product being clean coal and refuse. The dirt produced in the first washing can be further crushed and washed over again if necessary. A plant to treat 100 tons of slack per hour would, therefore, require a first bash with an area of 80 sq. ft., and a second bash with an area of 100 sq. ft.; the water in circulation would be about 130,000 gallons per hour, and the make-up water required about 2,500 gallons.

The rhéolaveur consists of a series of troughs of steel, cement or wood, sometimes lined with tiles, fitted with a series of pockets with adjustable discharges and, for the coarser sizes of coal, with upward water flows. These are arranged so as to discharge clean coal, refuse or middlings for re-washing as may be required. The plant is relatively cheap, compact and efficient and can treat all sizes from 4 in. to slurry. No general figures can be given as the plant has to be specially designed for each case. It is largely used in Belgium, and altogether about 60 million tons of coal a year are treated by it.

At Grassmoor Colliery a rhéolaveur plant treats 100 tons per hour 0-1 in. in two sizes, 40 tons 0-$\frac{5}{8}$ in., 60 tons $\frac{5}{8}$-1 in., absorbs 105 h.p., uses 140,000 gals. water in circulation.
(*A. Audry, Proc. So. Wales Inst. Eng.*, vol. xli., p. 567.)

(See 'The Rhéolaveur Coal-Washer in Belgium,' by H. Briggs and H. Louis, *Trans. Inst. Min. Eng.*, vol. lxxiv, 1928, p. 285; also 'The Operation of a Small-coal Washer,' by C. E. Pulford, *Trans. Inst. Min. Eng.*, vol. lxxviii., 1929, p. 47.

In the United States small coal is being largely washed on shaking tables of the Wilfley type; such a table will treat 5 to 8 tons per hour of coal under $\frac{1}{4}$-in. mesh, requiring about 1 h.p.

The flotation process has been applied to washing fine coal. (See *Trans. Inst. Min. Eng.*, lxvii. p. 374.) It is being extensively used in Spanish collieries.

The Chance process employs a separating cone worked with a sludge consisting of sand and water; it is said to give excellent results on Anthracite, and is used in the U.S.A. (See *Trans. Amer. Inst. Min. Met. Eng.*, vol. lxx. p. 740.)

One of the principal difficulties in coal washing is presented by the fine coal (say $\frac{1}{30}$ in.), which forms slurry when suspended in water; it consists often largely of fusain, and is therefore non-coking and is often very impure. It may be collected in settling tanks, which, however, occupy much ground space. Most makers of washing plant supply an elevated conical settling tank, from which a thickened slurry can be drawn off from the bottom, whilst tolerably clean water is drawn off from the top. A still better device is the Dorr Thickener, usually between 50 and 100 ft. in diameter, though made up to 200 ft. diameter and about 10 ft. deep; the stirrer makes 4–8 revs. per hr., and 100 sq. ft. of thickener area are allowed for each 25 gals. per min. The Rheolaveur deals efficiently with all but the finest slurry. A recent device is the Kirkless Slurry Separator, which filters the slurry. It is generally considered preferable to blow out the dust or draw it off by an aspirator before the coal goes to the washery if the coal is dry enough. The dust is collected in cyclones, bag filters, etc., and is generally very suitable for dust firing though it may need further grinding for this purpose.

Dry Cleaning.—The American Coal Cleaning Corporation's machine consists of a shaking table with riffles and a porous deck through which a current of air ascends on the principle of the Sutton-Steele table; this cleans dry coal and the finished product contains under 2 per cent. of extrinsic ash. Over 10,000,000 tons of coal were cleaned in this way in 1927 in the U.S.A. (See *Trans. Amer. Inst. Min. Met. Eng.*, vol. lxx. p. 758.)

The largest American plant is the McComas plant at Crane Creek Mines, W. Virginia, treating 225 tons per hour.

This table has been introduced into England by the Birtley Iron Company, Ltd. Its first form, known as the Birtley SJ Table, has been erected in a number of places, one of the first being at Wardley Colliery, Co. Durham. This plant treats coal under $2\frac{1}{2}$ in. and consists of six SJ tables with dust aspirator and baghouse. It cleans to within 2 per cent. of the intrinsic ash leaving about 1 per cent. of free coal in the refuse. Its original capacity was 125 tons per hour, but this has now been increased.

An improved form, known as the Y Table, was introduced about 1926, having double the capacity of the SJ Table, and not needing as close sizing. Quite recently a still newer form known as the V separator, made in two types, the standard V and the super V, has been introduced; the former has about three-fourths of the capacity of the latter, which is as follows on average coal:

2 in. to $\frac{1}{2}$ in.	60 tons per hour
$\frac{1}{2}$ „ „ $\frac{1}{8}$ in.	40 „ „
Below $\frac{1}{8}$ in.	20 „ „

The power consumption for the fan and drive of these machines averages about 0·75 h.p. per hour. The Birtley Company has constructed some eight plants in England, eight more are under construction, and the total operating cost including labour, maintenance, and repairs is given at about 2·25*d.* per ton. (See papers by K. C. Appleyard, *Trans. Inst. M.E.* vol. lxxiii, 1927, p. 404, and World Power Fuel Conference, 1928, No. C 7.)

Another table used recently to some extent in this country is the Static dry cleaner of G. Raw. It consists of a long relatively narrow table, without riffles, but with three skimmers; the bed of the table is, like the last, of perforated material, but a pulsating current instead of a continuous current is introduced into the air-chest beneath the bed. The tables have capacities of from 30 to 50 tons per hr. and the power consumption is 0·85 B.O.T. unit for a ton of coal. Costs including labour, power, maintenance, interest and depreciation, are given at $3\frac{1}{4}$*d.* per ton (see paper by G. Raw and F. F. Ridley, World Power Fuel Conference, 1928, No. C 6). Another dry coal-cleaning table is the Kirkup table, in which the table is at rest, but receives a pulsating air current beneath its perforated bed. The Peale-Davis table is like a Birtley Y table, 40 ft. long, 14 ft. wide, with a capacity up to 250 tons per hr. This is being used at a Yorkshire colliery.

In some cases dry cleaning may with advantage be combined with washing, the coal below, say, ⅝ in. going to a dry-cleaning plant and the coarser coal to a washery; the washed coal after drainage is mixed with the dry-cleaned coal and the product carries a proportion of moisture suitable for many purposes.

(See also 'The Dry Cleaning of Coal,' by H. Louis, *Fuel Economy Review*, 1928.)

Dust is now often removed from coal that is not naturally too wet before it is cleaned by washing or dry-cleaning; it may be screened off by fine vibrating screens or may be taken out by an air current either on the screens or on the dry cleaning tables or else in a dust extractor; the dust is collected by cyclones and bag-houses and is often used for dust-firing. Wedge wire is often used for the fine screens. The Waring dust collector is being used successfully. (See *Min. Mag.*, Dec. 1928.)

Vibrating screens have a tightly stretched screening surface kept in rapid vibration and set at a tolerably steep angle; the Hummer, Hayle, Overstrom, etc., screens differ mainly in the mechanism by which the vibration is produced.

For a good comparison of different methods of coal-cleaning see paper by Wheeler and Chapman in report of the Coal-Cleaning Conference at Edinburgh, July, 1927, pub. by Soc. Chem. Ind.

Mr. Norman Kemp has applied *X*-ray analysis to the products of the coal washery.
(*Trans. Inst. Min. Eng.*, vol. lxvii. p. 59.)

Magnetic Separation.

Maxima of magnetic susceptibility of minerals by volume in C.G.S.

Soft iron		400

Common non-ferrous minerals, *e.g.* mica, quartz, felspar, calcite, have susceptibilities < 0·000001. 'Strongly' magnetic minerals have susceptibilities > 0·001. 'Feebly' magnetic minerals between 0·001 and 0·0001. (*After Prof. Ernest Wilson.*)

Magnetic separators: (1) For minerals of high magnetic susceptibility:—

Dry working, *e.g.* Wenström: drum 30 ins. diam., 24 ins. face. Capacity 5–7 tons per hour; will take lumps up to 7 lbs.; 30 r.p.m. Current 15 amperes at 120 volts.

Wet working, *e.g.* Gröndal: 24 ins. wide, 24 ins. diam., 100 r.p.m. Capacity up to 3·5 tons per hour. Current 10 amperes at 110 volts.

(2) For minerals of low magnetic susceptibility:—

Dry working, *e.g.* Rowand-Wetherill. Belt 18 ins. wide, three electro-magnets taking respectively 5, 15, and 30 amperes at 110 volts. Capacity, 0·25 to 1 ton per hour.

Wet working, *e.g.* Ulrich.

THE RAPID MAGNETTING MACHINE CO., LTD., MAGNETIC SEPARATORS.

(The Rapid Magnetting Machine Co., Ltd., Birmingham.)

When choosing a magnetic separator the greatest possible care should be exercised. The test method, which is, without exception, adopted by mineral mining concerns, is to send a reasonable size *normal* sample of the material to be treated, accompanied by information likely to be useful, as, for instance, the quantity to be treated per hour, voltage of current (D.C.) available, whether to be self-contained with feed attachment, space available, etc., etc., and inquirers should insist on the magnetic products being returned for examination for cleanliness.

Specification should be compared with specification, even after material has been tested, as a machine efficient as regards the actual extraction may be of such unsuitable design as to cause a constant loss of material being treated; and, where iron is to be removed as an impurity, guarantees of *efficient* output should also be obtained.

For feebly magnetic minerals the magnetic separators have to be of a special type. For such minerals the 'Rapid' (Thompson-Davies) Patent Ore Separator (dry-working) machine has been designed; this machine is 4 pole, 3 disc, 15-in. belt; the maximum current on each pole is 2½ amps. at 110 volts capacity. The machine will deal with about 3 tons of wolfram-tin per day, monazite sands 5 tons per day, but the capacity varies according to the characteristics of the ore.

Flotation Processes.

These may be classified as follows:—

I. *Film Flotation*, utilising differences of surface tension on particles at an air-water interface—*e.g.* De Bavay, Macquisten processes.

II. *Oil Flotation*, utilising differences of surface tension in an oil-water medium where the particles are buoyed up by oil—*e.g.* First Elmore process.

III. *Adhesive Processes*, utilising differences of surface tension between particles and oil or grease, causing differential adhesion to oiled or greased surfaces—*e.g.* Murex, Cattermole, greased-plate processes.

IV. *Froth Flotation*, utilising differences of surface tension at gas-water interfaces, where the particles are buoyed up by bubbles of gas:—

(*a*) Where the bubbles are produced by chemical action—*e.g.* Potter, Delprat processes.

(*b*) Where the bubbles are produced by releasing the air dissolved in water—*e.g.* Elmore vacuum process.

(*c*) Where the bubbles are produced by mechanical means—*e.g.* Minerals Separation, Callow, Janey, K. & K. (Kraut & Kolberg), Rork, Kleinbentink, Ekof, processes.

(See 'Froth Flotation: its Commercial Application and its Influence on Modern Concentration and Smelting Practice,' Walter Broadbridge, *Trans. Inst. M. M.*, vol. xxix. p. 205, 1920. 'A Contribution to the Study of Flotation,' H. L. Sulman, *Ibid.*, p. 44. 'The Concentration of Ores by Flotation,' H. L. Sulman, *Bull. Inst. M. M.*, Aug. 1930. 'Flotation Reagents,' B. W. Holman, *Bull. Inst. M. M.*, Nov., 1930.)

(Ralston.)

Reagents used:—

Gangue modifying:—Acids, alkalies, silicates carbonates, and other salts.

Froth producing:—Soluble oils, essential oils, cresylic acid, amyl alcohol, etc.

Froth stabilising:—Insoluble oils, petroleum, etc.

According to figures collected by the United States Bureau of Mines, a total of 50,073,450 tons of ore was treated in the United States by the flotation process in 1927. By far the greater portion, 40,881,768 tons, consisted of copper ores. The remainder was made up of complex lead-zinc, lead, zinc, copper-iron, and miscellaneous ores. A total of 220,514,373 lbs. of reagents was consumed in the treatment by flotation of all classes of ores. The bulk of this consumption was lime, of which 169,926,145 lbs. were consumed. Pine oils constituted the greater portion of the frothing reagents used, accounting for 5,064,320 of a total of 6,583,151 lbs. Appreciable amounts of cresols were also used. Of the oils used as collecting reagents, coal-tar creosotes and coal tar made up 2,655,352 of a total of 3,508,993 lbs. Other oils used as collecting reagents were wood-tar creosote, crude oils, and petroleum products, blast-furnace oils, water-gas oils and tars, and miscellaneous and reconstructed oils. Ethyl xanthates and di-thio-phosphoric acids were used as collecting reagents to the extent of 3,319,639 lbs. and 1,932,996 lbs. respectively, and made up the great bulk of chemicals used for this purpose. Other chemicals used were higher xanthates (amyl and butyl), thio-carbanilide, alpha-naphthylamine, thio-ureas, and oleic acid. The acids and alkalis used in addition to the great consumption of lime were composed of sulphuric acid, hydrochloric acid, sodium carbonate, sodium bicarbonate, sodium hydroxide, barium carbonate, and cement. Other inorganic reagents used included sodium sulphide, calcium and barium sulphides, copper sulphate, cyanides, sodium sulphite, sodium silicate, zinc sulphate, sodium dichromate, tri-sodium phosphate, aluminium sulphate, sulphur, calcium chloride, and sodium chloride. Some quantities of glue and starch were used as protective organic colloids.

(*The Chemical Age*, July 6, 1929.)

Surface Tension of Liquids against Air.

	Dynes per sq. cm.			Dynes per sq. cm.
Water (at 0° C.)	75·8	Water with 0·14 per cent. cresol	(at 23° C.)	71·5
Water (,, 20° C.)	75·1			
Phenol (,, 41° C.)	37·0	Water with 0·14 per cent. amyl alcohol	(,, 23° C.)	68·4
Cresol	34·8			
Olive oil	32·0	Water with 0·134 per cent. saponine	(,, 23° C.)	48·7
Petroleum	27·7			
Turpentine	25·6	Water with eucalyptus 'solute'	(,, 20° C.)	44·6

Dilute sulphuric acid reduces the contact angle and hysteresis range of that angle far more for quartz, silicates, and oxides than it does for metallic sulphides; oiling the latter greatly increases the contact angle and the hysteresis range.

(*H. L. Sulman*, 'A Contribution to the Study of Flotation,' *Trans. Inst. Min. Met.*, vol. xxix, 1920.)

The Inspiration Consolidated Copper Company's plant at Miami, Arizona, treats 15,000 tons in 24 hours. The ore contains 1¾ per cent. of copper, mainly in finely disseminated sulphides. Flotation reagents used, 1¾ lbs. per ton of ore. Recovery, 85 per cent. of total copper, 90 per cent. of copper present as sulphide; concentrates contain 20 per cent. of copper.

(*Trans. Amer. Inst. Min. Eng.*, lv., 1916, p. 576.)

Selective flotation is very largely employed for the treatment of lead-zinc ores in the Western States and in Mexico. (See 'Selective Flotation as Applied to Canadian Ores.' C. S. Parsons, *Canad. Min. Journ.*, 1927, vol. xlviii, p. 468; also 'The Trend of Flotation,' Weinig & Palmer, *Colorado Sch. of Mines Quart.*, 1926, vol. xxi., No. 2.)

Finely ground coal may be froth-floated from shale, using 1 lb. of cresol and ½ lb. of paraffin, per ton of coaly shale; the shale contains about 65 per cent. of ash, the clean coal about 8 per cent. Petassic Zanthate is also used.

ELECTROSTATIC SEPARATION is used in some special cases—*e.g.* for concentrating rosin blende, molybdenite, and graphite (Blake-Marsden and Huff processes).

DRY SEPARATORS, using currents of air instead of water, are used under exceptional conditions.

FLOW SHEETS.

The diagrams given on pp. 2629–2637 are specimen flow sheets, illustrating the sequence of operations in certain typical cases:—

GOLD MILLING.

With the improvements in the cyanide practice and also with the exhaustion of the rich free milling surface ores of various camps, which rendered such improvements necessary, have come changes in the process of treating gold ores. Instead of the simple Californian practice of crushing by 900 lb. stamps to about 40 mesh, amalgamating either in or outside the battery, concentrating the sulphides on vanners or shaking tables, chlorinating the concentrates, and sometimes treating the tailings by cyanidation, the 'all-sliming' process has come into force.

As practised on the Rand, the ore is screened through grizzlies with bars 2¾ ins. apart, the oversize going to a sorting belt, thence to a crusher. The ore passes into a feeder, thence to stamps weighing 2,000 lbs. per head, where it is crushed to pass a 10-mesh discharge screen. The pulp is classified in cones and the coarse product delivered to tube mills where it is slimed. The product of the tube mills, together with the overflow from the classifying cones, is delivered to the amalgamating tables. From the tables it is again classified, the sands being cyanided direct, and the slimes treated by air agitation, then filter-pressed or vacuum-filtered.

The most vital changes from the old practice to the new have been: the use of the heavy gravity stamp merely as a preliminary coarse crusher for the tube mills; the adoption of the tube mills for fine grinding and the employment of the tall, air-agitation tanks and of filters.

The practice is modified in each district, the modification depending largely upon the nature of the ore. In some camps silver ores are being successfully treated by fine crushing and cyaniding.

CYANIDE PROCESS.

This process may be conducted in a number of different methods, which may be classified as follows:—

I. Coarse crushing and direct cyanidation (exceptional).

II. Fine crushing with:—

A. Simultaneous cyanidation.

B. Subsequent cyanidation without classification.

C. Subsequent cyanidation, preceded by classification into (*a*) sand, (*b*) slime.

(*a*) Sand cyanidation, generally by percolation.

(*b*) Slime cyanidation, performed by

1. Decantation.
2. Agitation (mechanical or pneumatic) and filtration.
3. Direct cyanidation in filters.

D. All sliming methods with simultaneous or subsequent filtration.

(*H. Louis*, '*Handbook of Metallurgy*,' i. p. 1031, 3rd edn., Schnabel and Louis.)

Filtration methods may be classified as under:—

I. Suction filters, divided into:—

(*a*) Filters forming a thin cake, continuous acting.
(*b*) Filters forming a thick cake, intermittent.

II. Pressure filters, divided into:—

(*c*) Ordinary filter presses.
(*d*) Sluicing filter presses.
(*e*) Filtering chambers or cylinders.

III. Centrifugal filters.

(*S. J. Young*, '*Trans. Amer. Inst. M.E.*,' xlii., 1911, p. 752.)

Precipitation is performed by zinc shavings, zinc-lead shavings, zinc dust, aluminium, electrolysis.

An average cyanide plant may be roughly estimated to cost complete $1,000 per ton treated per day in the Western States. An average cost of cyaniding, including crushing, is now about $1.50 per ton, but varies within very wide limits.

Stamps.

The duty of stamps depends upon the nature of the ore, the weight of the stamp, its speed and drop, the size of the aperture of discharge screen, and the height of the discharge. The following table gives the duty per stamp in various districts :—

DUTY OF STAMPS.

Mine or District.	Weight of Stamp.	Drop in Inches	Number of drops per Min.	Screen Aperture.	Discharge in Inches.	Tons Crushed per head per 24 Hrs.	Remarks.
California . .	900 lbs.	7	90	900 per sq. in.	4	3	Gold Quartz
Melones, Cal. .	1,000 ,,	7	104	20 mesh	—	4·41	
Tonopah Mill, U.S.A.	1,050 ,,	6½	104	slot ·04 in. wide	2½	5·09	Gold and Silver
Montana-Tonopah, U.S.A.	1,050	7	100	20 mesh	3	3·3	Gold and Silver
Tonopah Belmont, U.S.A.	1,050 ,,	6	104	24 mesh	—	3·7	,,
Goldfield, U.S.A..	1,050 ,,	7	108	12 mesh	—	6	,,
Komata Reefs Mine	1,030 ,,	6½	100	4½ holes per in.	4	5	Gold
Luipaards Vlei Rand	1,629 ,,	8½	98·6	200 holes per sq. in.	4	9·6	,,
Simmer & Jack East	1,550 ,,	8	96	200 holes per sq. in.	3½	8·3	,,
Waihi Grand Junction	1,110 ,,	7	105	5 to 10 mesh	1½	7·6	,,
Oroya Brownhill.	1,100 ,,	7½	108	10 mesh	2	6·48	,,
Ivanhoe . .	1,192 ,,	7½	104	225 mesh	2	5½	,,
Gt. Fingall . .	1,150 ,,	8	106	12 mesh	3	7	,,
Mysore Gold Mine, Mysore, India	1,150 ,,	7·5	96	1,200. 625 and 400 per sq. in.	3	3·63	,,

It is claimed that the new 2,000 lb. stamps of the Goldfield (S.A.) are capable of crushing 26 tons of ore per stamp per 24 hours by introducing an elimination screen to 'bypass' the fine material from the rock bins direct to the tube mill and using screens with aperture of ·284 inch.

Amount of water varies on the Rand, from 5 to 10 tons of battery water to one of ore, depending upon the duty. In Western Australia the amount of water required is 4 to 8 gallons of water per stamp per minute.

Power per stamp.—The 2,000 lb. stamp requires 5 h.p. per stamp. In Nevada, for 1,250 lb. stamp 3·5 h.p. per stamp is used. At the Goldfield Con. in Nevada with 140 stamps, fine grinding and cyaniding 1,500 h.p. is supplied to the mill or 1·73 h.p. per ton of ore milled.

COST OF EQUIPMENT OF GOLD MILLS.

The following is the comparative cost of gold mills, including all machinery and buildings .—

Mill.	Number of Stamps.	Cost of Machinery and Plant.	Cost per Stamp.
Rand Mill	200	£334,000	£1,670
New Kleinfontein	200	420,480	2,102
Wit Deep	200	346,210	1,731
Robinson Central Deep . .	100 and Tube Mill	234,013	2,340
Great Fingall	,,	193,745	1,937
El Oro	,,	160,000	1,600

In Nevada, the cost of complete plants doing fine grinding and slimes filtering is 1,400*l.* a stamp.

Tube Mills

are used as secondary crushers following the stamps. On the Rand they are most efficient when fed with ore that has been crushed through a screen the apertures of which are ·27 in. or say ¼ in. They are here 25 ft. in length by 5½ ft. in diameter, and one tube mill crushes the product of 10 stamps. Each tube mill requires 100 h.p. to drive it. In New Zealand tube mills are 16 ft. by 4 ft. revolving at 29 r.p.m., and driven by 25 h.p. motor. The feed is 1½ parts of water by weight to 1 part of ore. In 22 months a tube mill ground 28,500 tons of hard quartz, 50 per cent. of which passed through a 200-mesh screen.

At Pachuca 90 h.p. is used for a 5 ft. 6 ins. by 22 ft. tube mill. Output 140 tons per day through a 60-mesh screen.

At Waihi Grand Junction tube mills 19 ft. 3 ins. long by 4 ft. 8 ins. diameter require 42 h.p. Those 16 ft. 3 ins. long by 4 ft. 3 ins. diameter require 25 h.p. They consume 2·89 lbs. of flint pebbles per ton of ore crushed at stamps. They are run at 27 r.p.m.

Chilian Mills.

Chilian mills are employed either for crushing preliminary to amalgamation, in which case the gold is partly amalgamated in the mill itself, or they are used in lieu of the tube mill as fine grinders following the stamps.

For crushing ores for direct amalgamation the so-called slow speed Chilian mills are well adapted. Machines of this type are extensively employed in Russia and Siberia. They are expensive in first cost, but the power, labour, and repair costs are very low. Furthermore they are notable for their simplicity, requiring little close or skilled attention.

A slow speed Chilian mill was employed in California on hard close quartzose gold ore. It ran at 8 to 10 r.p.m. It had four runners each weighing 1,200 lbs. travelling on a steel die 3 ins. thick with 5 ins. face and 7 ft. outside diameter, 4½ tons of rock in a tank above and sustained by the axles giving additional crushing weight. Twenty tons of ore per 24 hours were crushed with a 4 in. discharge, and 88·1 per cent. extraction obtained, 0·85 per cent. of the ore passed through a 100-mesh screen. One man per shift handled the mill. Cost of ore crushed 6*s.* per ton. Gasoline power was used consuming under heaviest load 2·17 gallons of distillate per hour. (*A. McLaren.*)

The standard type of Chilian mills used in Russia is 7 ft. to 10½ ft. in diameter with 2 runners 5½ to 6⅛ ft. in diameter, and from 7 to 12 ins. in width. The speed is 11 r.p.m. The discharge is 8 to 10 ins. Feed is about 1 in. and discharge screen slotted. The water is 6·5 to 10·1 times the ore in weight and duty is 16 to 24 tons per 24 hours. The power required is 7 to 12 h.p.

Rapid-running Chilian mills were used as fine grinders after the stamps in the Goldfield Consolidated mill in Nevada on fairly soft ore. There 140 stamps were in operation and six 6-ft. Chilian mills crushing from 4-mesh to 16-mesh were installed. These were operated at 32 r.p.m. Their capacity was 75 tons per 24 hours and the power required 35 h.p. each. The cost of crushing by these mills is given at 5*d.* per ton of ore milled. (*J. W. Hutchinson.*)

At Cripple Creek a 6-ft. Chilian mill running at 33 r.p.m. reduces 4 tons of ore per hour, 60 per cent. of which will pass a 150-mesh screen. The feed passed a ⅛-in. aperture.

Rolls.

Where a relatively small tonnage is to be crushed coarse, as for example when coarse concentration is employed or where the ore is porous and is cyanided coarse, it is the practice to use rolls. They are cheaper than gravity-stamps in first cost, repairs, labour, and power, and are not complicated by screens.

In South Dakota the ore, a hard, close-grained Cambrian quartzite, carrying from 5 dwts. to 7 dwts. per ton, is crushed by rolls. The ore is fed to two 16- by 36-in. rolls used as cracking rolls and two others of the same size are used as finishing rolls. The final product goes through a ⅛-in. mesh direct to the cyaniding vats. The rolls require 100 h.p. The milling and cyaniding cost is 2*s.* 2*d.* per ton and 14,800 tons of ore are treated monthly.

THE

"MACHINERY MARKET"

ESTABLISHED 1879

A Commercial Engineering Journal
Published every Friday
Price 3d.

USEFUL TO

Every Business Man interested in Machinery.
Every Maker wishing to sell his Products.

GUARANTEED CIRCULATION

The Circulation of the "Machinery Market" is guaranteed. The minimum is 6000 copies weekly.

WIDE RANGE OF SUBSCRIBERS

Subscribers to the "Machinery Market" represent practically every industry in which machinery is employed.

SERVICE DEPARTMENTS

Free Questions and Answers Department. An Inspection Department. Deposit Payment System (whereby buyers can deposit purchase price with this Journal until they are in receipt of the goods ordered).

SALES SUPPLEMENT

Containing the largest list of new and second-hand machinery for Sale or Wanted of any Engineering journal.

Ball Mills.

Krupp ball mills are used extensively in Kalgoorlie where 44 are at work. Size No. 5 will crush up to 45 tons of ore per day consuming 25 h.p. No. 8 will crush 90 tons per day requiring 50 to 60 h.p. About 45 per cent. of the product from a 25-mesh screen will pass 150-mesh. It is charged with 1 or 2 tons of steel balls and revolves from 21 to 25 times per minute. They work well on either wet or dry ores. The wear and tear of liners, hunch and scoop plates cost 4·64*d.* per ton milled.

Milling Costs.

The following are the milling costs of different stamp mills :—

Mill.	Stamps.	Tons Crushed Monthly.	Cost of Milling per ton.	Rate of Wages per day.	Remarks.
Tonopah, U.S.A.	100	15,000	12*s.*	18*s.*	Silver Gold ore
Goldfield Con., U.S.A.	140	29,500	9*s.*	18*s.*	Silver Gold ore
Ivanhoe	100	16,600	8*s.* 9*d.*	12*s.* to 14*s.*	Bromo-cyanide treatment of slimes
Oroya Brownhill	50	8,950	17*s.*	12*s.* to 14*s.*	Bromo-cyanide treatment of slimes
Gt. Boulder	—	14,800	12*s.* 4*d.*	12*s.* to 14*s.*	Dry crushing with Griffin mills. Roasting.
Melones, Cal.	100	12,000	1*s.* 1½*d.*	10*s.*	Cheap power, labour and supplies
New Unified (Rand)	—	10,000	1*s.* 4*d.*	—	Milling only
Simmer East	—	—	2*s.* 6*d.*	—	Milling only

On the Rand, cost of milling of those companies using tube mills varies from 4*s.* 10*d.* to 8*s.* 8*d.* per ton of ore.

In California, with free milling ores and cheap water power, milling costs average from 2*s.* to 4*s.* per ton. In Alaska, with large tonnages of soft, free milling ore treated daily and no cyaniding or fine grinding the costs are about 1*s.* per ton of ore.

Horse-Power per Ton of Ore Treated per Day.

Type of Mill.	Mesh.	Horse-power.
Stamps and vanners	20 to 40	0·75 to 1·0
Coarse concentration	10 to 20	0·5 to 0·8
Combination-stamp	16 to 30	1·5 to 1·75
Chloridising stamp (dry)	to 16	2·0 to 2·5
Chloridising stamp (wet)	to 40	4·0 to 4·5
Magnetic separator	—	0·25 to 0·5
Cyanidation (dry) roll-crushing	20 to 30	0·5 to 0·8
Cyanidation (wet), stamp crushing and sliming	to 80	0·75 to 1·5

(*J. A. Barr*, 'Testing for Metallurgical Processes.')

Standards adopted by the Institution of Mining and Metallurgy.

1 oz. of fine gold = value 85*s.*
1 ton = 2,000 lbs. (avoirdupois).
1 miner's inch = a flow of 1½ cubic ft. of water per minute.
1 sluice head = „ 60 „ „
1 gallon of water = 10 lbs. at 34°.

Temperatures are to be expressed in centigrade.

Screen apertures and diameters of wire are equal, giving 25 per cent. screening area.

GOLD AND SILVER TABLES.

It is the practice of Continental and South American engineers to report the values of ore in grammes per metric ton. English engineers generally employ the method of quoting values in grs. and dwts., in some cases per long ton of 2,240 lbs., in others per short ton of 2,000 lbs.

TABLE for Conversion of Grammes per Metric Ton into Ducts, etc., per Long and Short Ton.

Grammes per Metric Ton.	Per Short Ton.		Per Statute Ton.		Grammes per Metric Ton.	Per Short Ton.		Per Statute Ton.	
	Dwts.	Grs.	Dwts.	Grs.		Dwts.	Grs.	Dwts.	Grs.

Alluvial or Placer Mining.

Deposits of auriferous or tin-bearing alluvial gravels are termed placers, alluvial drifts, or more simply alluvials. They are classified as shallow or superficial and deep-lying, sometimes called deep leads. Deep leads are accumulations of gravel from extinct or ancient rivers. They are mostly capped by igneous flows, as in California and Victoria, though sometimes they may be buried under recent gravels or drift, as at Lightning Creek, B.C., and the Lena Goldfields in Siberia.

The methods of mining used to exploit deposits of this character resemble pillar and stall in some cases and long wall in others. In California the gravel beds can be attacked by means of adits which also serve as drains for the large amount of water present. When the topography of the ground permits adits being used, the cost of mining is low, as at the Hidden Treasure, California, where the costs average 4*s.* 6*d.* per cub. yd. of gravel washed. In the Deep Leads of Victoria, where the pumping charges were unusually large (eleven million gallons per day being raised from one mine), the total cost per cub. yd. was 12*s.* to 15*s.* At the Lena Goldfields the total cost is from 20*s.* to 30*s.* per cub. yd. of gravel washed.

Superficial Deposits.—All gravel under 60 feet in thickness may be termed shallow or superficial gravels. Surface gravels are worked by the following methods:—

Panning.—A miner can pan ¼ cub. yard to 1 cub. yd. of gravel per 10-hour shift, depending on character of ground and nearness to water; 100 pans per day is a good day's work. Gravel in place is usually estimated at 3,000 lbs. per cub. yd., and the standard sheet iron pan 16 ins. diam. at top and 10¾ ins. diam. at bottom will hold 20 lbs.; 150 pans full will make a cub. yd. of dirt.

Rocker.—A man can rock ordinarily from 2 to 3 cubic yards of gravel per day, and save, in practical mining, 90 per cent. of the gold. In alluvial examinations the rocker plays a most important role, and is used in conjunction with the pan for determining the gold contents of any parcel of gravel. When used for this purpose, the design of the rocker differs slightly from that of the ordinary miner's rocker. A well-designed rocker, carefully employed, should save practically all the gold. The plans of most rockers, as published from time to time, are those of the ordinary mining rocker, which is too short, and set on too great a grade for use in saving fine gold. If much fine gold is present in the gravel, it will be advisable to use a strip of common Brussels carpet, laid along the floor of the rocker. This carpet is held in place by cleats and so can be easily removed in cleaning up.

Long Tom or short sluice can handle 3 to 10 cub. yds. of dirt per day, depending on the amount of water available and the character of the dirt.

Hand Sluicing.—Capacity of a sluice box depends upon the amount of water, grade of sluice, deposition of tailings, and character of gravel. No capacity can be given. Grade of sluice varies from 2 ins. to 21 ins. per box (12 ft.). An ordinary sluice box is made from 2-in. planks, and is 12 ins. wide by 12 ft. long.

Grade and Duty of Sluices.

Grade and Duty of Sluices.—The relation of actual width to the best ratio of quantity may not be very significant, but there is a notable increase in efficiency in passing from the smallest widths to the larger, and boxes less than 1 ft. wide are to be avoided, especially if the gravel is coarse. Treating 30- to 40-mesh sand on a 1 per cent. grade (say 1½ in. per 12 ft. box), one sluice head of water requires a channel 2 ft. wide to enable it to attain maximum duty. On a 2 per cent. grade, half a sluice head requires 2 ft. of width, the quantity of water required for maximum duty with a fixed width diminishing with increasing grade, but at what rate there are insufficient data to determine. Apparently the best width required for constant quantity of water varies directly as the grade. Coarser material requires a greater depth of water, and for 4 to 6 mesh gravel on a 2 per cent. grade, 1 ft. of width per sluice head is indicated. Variations up to 50 per cent. in the water make little difference to its duty, consequently the actual position of the optimum is not easily determined. Naturally the capacity of the sluice itself is correspondingly varied, and the mode of transportation and the saving are doubtless affected in any case.

The rate at which duty varies with slope is the resultant of so many variables that no law can be stated for all cases. In the neighbourhood of the best conditions the Utah experiments support the approximate rule that duty (water, width, and material being constant) varies as the 1·75th power of the grade. A single experiment with natural gravel on low grades by the U.S. Geol. Survey gave the 1·84th power. (*R. T. Hancock.*)

Good modern practice provides about 1 ft. of sluice-box width for every 2 cub. yds. of average material treated per hour, and 3,000 gallons of water per cub. yd. treated on a grade of 6 ins. to 12 ft.

Besides the ordinary feeding of sluice box by means of hand shovelling, many modified methods of feeding and disposing of tailings are employed. In Russia and Siberia the favourite method in use is to transport the gravel to and from the sluice box (here greatly modified from the plain open sluice box) by the employment of horses and small carts. This is a most expensive system and the yardage treated is small. Other variations are: the use of wheel barrows, tramming by cars, handling gravel by means of derricks, digging gravels by means of steam shovels, and loading into cars or direct into sluice, feeding sluice by means of scrapers operated by horses or steam power (drag-line scrapers).

The methods of preventing accumulation of tailings are to deposit them in running water or to remove them by means of drags, belt or link elevators, or hydraulic elevators.

HYDRAULIC MINING.

Hydraulicing proper is the method of mining by which jets of water under high pressure are thrown against a gravel bank, thereby undermining the gravel which falls, and is carried by the current into the sluice. The necessary pressure is obtained either by natural means, *i.e.* by conveying the water from some source having a greater elevation than the working face, or by pumping directly into the supply pipe by powerful pumps. In the former case water is conveyed to the working by means of pipes, flumes or ditches. Ditches are generally most convenient and economical for conveying water for long distances, but sometimes the nature of the ground is such (either too porous or too rocky and difficult to excavate) that a flume becomes cheaper. When lumber is abundant wooden flumes are built, but in many cases, especially in the tropics, where wood rots rapidly, sheet steel flumes are preferable. Steel flume per foot, including rivets, angle iron, etc., ready for transport, costs from 4*s.* to 11*.*; the sizes vary from a cross-section of 1·28 sq. ft. to 20·48 sq. ft. From the ditch or flume the water is fed through a strainer into a pressure box. From here, a pipe leads to the Y's, which in turn lead to the monitors or giants.

Monitors or Giants.

Monitors or Giants.—These are appliances consisting of a base for attachment to the pipe line and a long conical reducing piece, arranged with one or more joints so that it can be rotated in any direction horizontally and through a very wide angle vertically. The smaller or conical end is fitted with a nozzle butt to which different sizes of nozzles may be attached as circumstances may require. Modern giants are fitted with deflectors, attachments on the butts whereby the giant is turned or deflected by means of the force of the water itself. The high-pressure giants also have ball-bearing joints.

Nozzles from 2 ins. up to 10 ins. are used, working under heads or pressure from 100 up to 600 ft. or more.

The amount of gravel which can be washed down will depend upon its nature, upon the volume and pressure of the stream of water issuing from the nozzle, and is also dependent in no small degree upon the skill of the operator who handles the giant.

The following gives the approximate amount of gravel washed under various heads :—

Effective Head in Feet.	Size of Nozzle.	Flow in Cub. Ft. per Minute.	Approximate amount of Gravel in 24 hours in Cub. Yds.	Weight of Giant. Lbs.	Price of Double Jointed Ball Bearing Giant.
					£
100	2 ins.	104·88	160	120	28
200		148·32	230

(*Hendry.*)

Hydraulic Monitors and Pelton Wheel Jets.

J. J. Garrard (*Trans. I.M.M.* 1917) gives a table of discharges in cubic feet per minute for different sizes of nozzles and various heads derived from the formula : Delivery in cub. ft. per min. $= 3{\cdot}75\, d^2\sqrt{P}$, where d = diameter of nozzle opening in ins. and P = gauge pressure in lbs. per sq. in., or effective head $\times 0{\cdot}4326$. An equivalent formula given by him is $2{\cdot}468\, d^2\sqrt{h}$, where h = effective head in ft. The factor 2·468 allows for a nozzle contraction coefficient of 0·94 whereas Hendry's figures in the above table are based on the theoretical value 2·624, and make no such allowance.

Costs.

The costs per cub. yd. were at North Bloomfield 2·05*d.* per cub. yd .and at La Grange 3*d.*

In British Columbia one and a half million cub. yds. were mined and washed at a working cost of 0·97*d.*

In Northern California placer ground containing only 1·26*d.* per cub. yd. has been profitably worked. The amount of gravel washed was 1,251,399 cub. yds., yielding 6,330*l.* The profit obtained was 821*l.*

Hydraulic and other Elevators.

When a hydraulic mine possesses an insufficient slope of bed rock for moving material (the lightest grade permissible being 220 ft. to the mile) other methods of disposing of the gravel 'piped' must be employed. Where water under pressure is cheap and abundant the hydraulic elevators are employed. They are of the pipe type—either Hendry, Evans or Campbell and the Giant Elevator.

The pipe elevator operates on the principle of an injector. Water under pressure is discharged through a nozzle set within a steel jacket, creating a vacuum, and causing water and sand and gravel fed into intake to rise to a height corresponding to 10 per cent. of the head under which the water is applied.

Three sizes are made: 10-inch throat 3½–4½ inch nozzle, using 300 to 500 ins. of water; 12-inch throat 4½–5 inch nozzle, 500 to 750 ins. of water; 15-inch throat, 750 to 1,000 ins. They weigh about a ton and cost 250*l.*

In South Oregon, U.S.A., at the Weimer placer mine, two hydraulic elevators are employed to handle the gravels. One of them has a lift of 39 ft., and operating with a head of 330 ft., uses 11 cub. ft. of water per sec., besides taking all water from two No. 2 Giants. The second elevator has a lift of 9 ft., a head of 125, and uses 18 cub. ft. of water per sec. besides all the water from the first elevator. This makes a final discharge of 40 cub. ft. per sec.

Giant Elevators.

Besides undermining and cutting the gravel it has been discovered that gravel can be effectively 'driven' up a slope or incline to a raised line of sluices by means of the power of water under pressure. An elevator based on this principle is termed a 'stacker.'

In California a stacker was operated as follows: A chute was built sloping upwards at 30°. This was 4 ft. wide by 24 ft. long and constructed of 1½-inch planks. Riffles 2 ins. apart and with a drop of 2½ ins. between were laid across the bottom. These were covered by an iron grizzly. At the foot of this chute a 3-foot sump was dug in which was set up a hydraulic elevator with a 12-inch throat and worked by a 5-inch giant. This elevator, working under a 90-foot head, elevated to 16 ft. vertically the seepage, fine and water from two field-giants.

Twenty feet in front of the stacker was installed the 3-inch drive giant. Two 4-inch field-giants wash the gravel to the chute and the drive giant forces it up the stack, the fine material falling through the grizzly and down the riffles to the elevator, which raises it to the sluice-boxes.

The field-giants handled 600 cub. yds. per 24 hours, and the gravel could easily be raised to 25 ft. vertically by means of the drive giant. The cost of handling material exclusive of equipment was under 2½*d.* per cub. yd. (*S. S. Smith.*)

Ruble Elevator.

The Ruble elevator is constructed on the above principle, but it is more portable and does away with the hydraulic elevator. It is also self-contained, as the sluice-box is part of the machine.

In Idaho, U.S.A., this elevator has been tried with excellent results (*see* Porter, T.A.I.M.E., 1909, for a detailed description of this elevator). The following points are claimed to its merit: 1. It handles larger rocks with less water than other types of elevators. Handles boulders up to 1 ton in weight. 2. It dispenses with the boulder crew, either at the mine, ground, sluice-box or dump. 3. It saves the gold and the gold-saving department may be protected by lock and key. 4. The gravel is picked up in close proximity to the giants, the gold immediately extracted, and the boulders and other waste material dropped back on bedrock previously worked off, instead of being transported a long distance to the dump. It makes its own dump.

Mechanical Elevator.

In regions where water is neither cheap nor abundant, in handling gravel or tailings, resort must be made to some form of mechanical elevators. A mechanical elevator was erected some years ago on Bonanza Creek, Alaska. This was made of a frame of steel, 49 ft. high, mounted on wheels. The gravel was elevated by a bucket line of the close-connected type, 76 buckets in all, each with a capacity of 3 cub. ft. each. These discharged at a rate of 26 per min. directly into a sluice-box. The pit was drained by means of a 12-inch centrifugal pump, assisted by a hydraulic jet. The power was 200 h.p. in all, 35 for the bucket line and 165–175 for the pumps. The actual capacity per day was 1,500 yds. (*T. A. Rickard*). The first cost of this machine was high, and in actual running it proved costly in operation and repairs. Another machine of the same type, but employing a heavy dredge bucket, is being erected in Eastern Canada. No results of actual working are yet to hand.

Centrifugal Pumps.

Centrifugal Pumps as a means of elevating gravel and tailings have been extensively employed in Australia. It is claimed that with wood fuel at 7*s.* per ton of 50 cub. ft. and European rate of wages paid, to elevate tailings with pumps should not cost more than 2½*d.* per cub. yd. of solid. Thompson & Co., of Victoria, are the makers of gravel pumps suitable for this class of work. Their pumps vary in size from 3½ ins. to 16 ins. The capacity of solids per hour from 7 to 150 cub. yds. The indicated horse-power from 2½ to 583. The combined suction and delivery head from 10 feet to 100. An installation of this kind possesses the advantage of being cheaper to erect and easier to move than the belt or bucket type of elevators mentioned. However, where there is an undue amount of large stones present in the gravel, the latter type is preferable.

Pipe Lining.

Three rubber-lined pipes, each of 9 in. internal diameter and length of about 20 ft., have been in continuous operation on the discharge line from an 8-in. gravel pump at the Sungei Bari Mine, Malaya, for a period ranging from 18 months from the date of installation of the first pipe. These pipes have been subjected to a continuous flow of gravel, amounting to about 17,000 cub. yds. of solids per month, and a working pressure of about 17 lb. per sq. in. The three pipes, although differing somewhat in design, are all alike regarding the successful results of the rubber applied to them, there being little or no evidence of wear or abrasion on the rubber after this lengthy period of operation. The lining is of crepe rubber about ½ in. thick. The life of a lap-welded mild steel pipe ⅜ in. thick on the same line, with frequent turning to ensure even wear, does not amount to an average of seven months. ('*Mechanical World*,' Jan. 21, 1927.)

Dredging for Alluvial Minerals.

(Contributed by Harold E. Fletcher, A.I.N.A., M.I.Mar.E.).

The most important form of alluvial mining is dredging, for the recovery of gold, platinum, and tin. The greater part of the platinum recovered in Siberia and Russia is by dredging, and that of the tin in the Malay States. When all conditions requisite for successful working are present, when the ground has been properly proved * and a well-designed and effective dredge installed, then this type of mining is the safest and surest of all forms of mining investment.

Careful systematic boring is necessary to get true values. Dredging properties call for certain conditions, and unless these exist the success of the enterprise suffers. The conditions are :

(1) The presence of the mineral, which should be evenly distributed throughout the pay dirt.
(2) Sufficient ground to warrant the installation of at least one dredge.
(3) Soft bedrock, free from pinnacles.
(4) Absence of large boulders.
(5) Absence of permanently frozen ground.
(6) Absence of great amount of clay.
(7) Absence of heavy floods.
(8) Surface of an even contour, not too rough and broken.
(9) The ground should retain sufficient water to float dredge (50 miner's ins.), or available water supply from a river.
(10) The economic conditions, *i.e.* labour, transport, climate, vary inversely with amount of mineral in ground.

The life of a well-designed dredge may be calculated at from twelve to fifteen years, provided it is kept in good repair. Repairs for the first three years would be normal (excepting accidents), such as the replacing of bucket pins and bushes, ladder roller spindles and bushes, screen plates, tumbler bearings, and usual power plant replacements, and later on in the life of the plant tumblers and shafts, main gears, buckets, repairs to pontoon, etc.

Broad flood plains or ancient lake gravels form more suitable dredging ground than does deposit situated in narrow rocky gulches. Frozen ground cannot be dredged without preliminary thawing. Dredging of gravels lying in rapid rivers is risky, as there is always danger of losing the dredge by sudden floods. Gravels from 10 to 80 ft. below water and 20 ft. above have been successfully dredged.

The modern dredge consists of a hull or pontoon of wood or steel, upon which is mounted the digging device, a bucket ladder capable of being raised and lowered, the washing plant comprising screen, tables or launders, the pump, of the centrifugal type for water supply to screen and tables, the stacker or elevator to dispose of the tailings well astern of the dredge, and the power plant. The buckets raise the ground and discharge into the revolving perforated screen, the fines pass through the perforations on to the tables, and the stones and large material pass through the screen to the tail chute and on to the tailings stacker. The dredge can cut its own passage. The cutting depth and manœuvring lines are worked by special multi-barrelled winches, controlled by one man, the winchman.

'Suction' dredges are used at times; they are only successful in light and free ground with level bedrock. The power required has been found to exceed that of the bucket dredge of equal output. With the suction dredge it has been found difficult to control the surges of water that sweep the tables when the spoil will not draw easily. This type of dredge has not given good results on tin in the Straits of Malay.

'Bucket' dredges are classified in two types, the New Zealand and the American; the latter has been evolved from the former to suit conditions existing in California and other parts. The principle is the same, but the American type is associated with heavier construction, larger buckets of the close-connected type instead of open, spuds (adjustable piles) instead of a headline, the raised pilot (or central control house), and other modifications. Both types have their advocates and both their utility.

The New Zealand type was associated with open-connected buckets, moderate power, simple engine for driving all units and light construction, but to-day this type is built of fairly large capacity and heavier construction. In its smaller sizes for lighter ground its first cost is in its favour, also for prospecting work or proving a dredging property; also where difficulties of transport prevent the use of the heavier type of dredge.

Transport.—Dredges are generally shipped in pieces for re-erection, the steel pontoons being riveted and launched at site. The heaviest parts to transport are the main engine castings, the boiler shell, the tumbler castings (mostly steel), crown wheel castings, winch barrels, screen ends, etc. The 'Tumblers' weigh from 15 cwts. in the small to 15 tons in the large sizes; boilers stripped, from 3 to 10 tons; watertube boilers, the heaviest part being the steam drum, from 7 to 60 cwts.

Hulls.—These have to be strongly designed to stand the stresses. Wood pontoons are not entirely satisfactory and generally have to be replaced during the life of the machinery; they suffer damage by ice in cold countries, and are difficult to build to stand stresses, and much heavier than steel.

* See *Alluvial Prospecting*, by C. Raeburn and H. B. Milner. 1927.

Power.—Where wood and coal are plentiful, steam is cheapest. In Malay the Rawang coal (8,000 B.Th.U.) is used in water-tube boilers with chain grate stokers; steam pressure 160 lbs., and 100° superheat. Where oil is available at reasonable cost, it can be burnt under boilers or used in Diesel or semi-Diesel engines, and these have proved more economical than steam.

A gold dredge with 9 cu. ft. close-connected buckets is running in South America with semi-Diesel engines, also smaller dredges in Burma, etc. Full Diesel engines require the services of a specially skilled engineer. Several of the recent tin dredges have Diesel-electric generating plant on board running electric motors. Producer-gas plant and engines are used in Burma, Malay, Africa, etc., running on charcoal, driving direct or driving generators to supply current to the several motors. Where electric current is available and power can be transmitted to the dredge by cable at reasonable cost, and transformed on the dredge to the required voltage, it is in favour of low running costs, but it is generally accepted that it does not pay to build a special generating plant unless the ground will carry four or more dredges. Waterfall power to generate current is also being used.

The horse-power installed on gold and platinum dredges varies according to the capacity of bucket, dredging depth, etc. The distribution of power is generally as follows:

Bucket chain . .	33% of total power.	Screen . . .	10% of total power.
Water-pump . .	30% ,, ,,	Elevator . . .	12% ,, ,,
Winch . . .	15% ,, ,,		

On tin dredges, where larger water supply is necessary and higher water pressure, the pump power proportion is larger. On large dredges a separate winch is often fitted to deal with the bucket ladder.

Gold Dredges.

Larger types of American design are used in America, Siberia, etc., in addition to the open-connected type. Gold is saved on tables covered with cocoanut matting and expanded metal; the gold by reason of its heavy specific gravity settles in the mats, the dirt being washed down the tables overboard, the mats being taken up at periods and washed. With properly designed tables and adjustable water supply, quite fine gold can be saved. Platinum is easier to save owing to its heavier specific gravity.

Tin Dredges.

Of recent years these have increased in size considerably. The difficulty is not in raising the ground, but in treating it efficiently; the tables require to be of large area and the water supply larger than for gold dredging. Tables or 'launders' are generally from 3 to 4 ft. wide and up to 80 and 100 ft. long, wood riffles are fitted, and the wash agitated gently by hand-raking or mechanical means to allow the tin to sink through the wash and settle on the bottom of the launders. Owing to the large area of the tables the pontoons are of larger dimensions than for gold dredges; tables up to 7,000 to 8,000 sq. ft. area in two tiers are in use. Owing to the difficulty of carrying such tables, some of the latest dredges have been designed with jigs and classifiers, or a combination of riffles, launders, jigs, and classifiers, which will allow of better treatment and the saving of finer tin. The use of jigs allows of better saving adjustment. With skilled attention, up to 92 per cent. of the boring values have been obtained. Clay in the ground in both gold and tin dredging presents great difficulty to the dredge designer, and to break it up and release the values it contains call for special arrangements, such as puddlers, high water pressure, etc.

Where large boulders or heavy clay is met with a 'tray' connected bucket chain is sometimes used, the trays being castings equal to the base of the buckets and contributing in output each about 25 per cent. to 30 per cent. of the bucket capacity.

The design for tin dredges is tending towards the American type in regard to the design of the driving gear, buckets, tumblers, winches, etc. The latest dredges have close-connected buckets of cast manganese steel and nickel-chrome steel pins, cast manganese tumblers, etc.

There has been a vast amount of capital put into tin dredging in the Malay States and Siam, the number of dredging plants reaching towards 200. Some of these companies have paid 25 per cent. dividend for a number of years.

The largest English-built dredges have close-connected buckets of 12 cu. ft. capacity, a large proportion 8 and 9 cu. ft. The open-connected dredges range from 6 to 15 cu. ft. buckets.

Dredging depth ranges from 30 to 80 ft., and dredges have been built to dig 120 ft.

Output varies according to bucket capacity and the rate at which the ground can be efficiently treated. The open-connected bucket is run from 14 per minute for the smaller to 12 per minute in the larger sizes. The close-connected bucket from 28 to 18 per minute.

Maximum output is calculated:

$B \times S \times 60 \div 27 =$ cu. yds. max. per hour.

B = capacity of buckets in cu. ft.

S = number of buckets delivering per minute.

27 = number of feet per cubic yard.

Roughly, 1 cu. yd. is calculated 1½ tons.

To obtain the estimated output, one-third is deducted from the maximum, but this is not always reached; buried timber and large boulders tend to decrease output. The removal of barren overburden (to reach pay dirt) and difficulties of cleaning up bedrock lessen the profitable dredging time. A further factor is time lost in cleaning up the tables or launders to recover the gold or tin. Working time varies; many dredges have averaged over 600 hours per month.

Working costs vary with difficulties of ground, cost of fuel, and labour.

Comprised in above are European and native labour, fuel, stores, spares, camp upkeep, passage money and leave pay, management expenses, depreciation of plant, insurance.

The aggregate cost of running a small dredge does not vary greatly from running a larger one, and ground that is too low in value to give a return on a small dredge could be made to pay with a dredge of large output. With favourable conditions, dredges on easy ground have been run for as low as 1·5*d.* per cu. yd. treated. Large tin dredges in Malay 3·13*d.* to 4·0*d.* per cu. yd. treated.

TIN DREDGES.

Bucket Cap.	Type.	Monthly Output in cu. yds.	Working Hours per Month.	Dredging Depth.	Pontoon.	Steam. H.P.	Net Weight.
				Ft.	Ft. Ft.		Tons.

6	60,000	40	280	16,000	—
7	74,000	32	350	20,000	180

The Californian or American dredge is costly, very heavily built, with close-connected buckets, digs with spuds, and till lately built with wooden hulls.

For properties where the transport is high, as in parts of Siberia, and where heavy repairs are difficult, a well-built New Zealand type of dredge, with ample stock of spares, is preferable. Indeed, its choice is imperative in some cases, for the high transport costs to some properties exclude the use of the ponderous American type of dredge. On the other hand, cheap transport, access to machine shops, and with heavy or stiff semi-cemented gravel, or large deep deposit of fair digging gravel (the latter permitting the handling of enormous daily yardages) are conditions favourable to the use of the American dredge.

CALIFORNIAN TYPE DREDGERS (GOLD).

SECTION XXXIX

PART II

MINERAL VALUATION.

(By Professor Henry Louis, M.A., D.Sc., A.R.S.M., M.Inst.C.E., etc.)

General Principles.

Under the head of Mineral Valuation are included two somewhat different valuations, namely, that of a mineral property, whether worked or not, and that of a mine as a going concern; the difference arises from the fact that the proprietor of the minerals does not as a rule work them himself, but disposes of them, usually for a royalty, to the mine-owner who works them. In cases where the mine-owner is also the proprietor of the minerals, it is generally more convenient to value the mine, the royalty derivable from the ownership of the minerals being included as a part of the profit derivable from the mining operations.

In either case it is necessary to determine the present value of a number of annuities, the latter being the annual revenue derived from the royalties or the profits, as the case may be.

The amount of the royalty per ton is generally known or can be closely approximated, being the price paid or to be paid for the mineral in its unsevered condition as it lies in the deposit. (For a full discussion of the nature of royalties see *Trans. Inst. Min. Eng.*, vol. lxxiv. 1927–8, p. 277.)

The profit per ton must be estimated from the probable cost of working and the probable value of the mineral in its marketable condition.

The tonnage to be wrought annually must be estimated, having due regard to all the conditions of the deposit, and should be taken to be the amount that can be extracted, so as to produce the maximum total profit over the period under consideration. It is obvious that a deposit worked out with excessive rapidity will yield no profit when the interest on the capital outlay required to so work it exceeds the profit derivable from working; on the other hand, if worked excessively slowly, the standing charges may exceed such profit. Between these extremes lies the rate of economic working; it will generally be found that there is a considerable range of working rate, within which the economic results are practically uniform, and the best rate within that range is usually determined by market conditions or other purely commercial considerations.

The probable total quantity of mineral that can be economically produced from the property must next be calculated, meaning thereby the amount which is as likely to be exceeded as to be fallen short of; it is obvious that the quantity that can actually be produced from any property can never be known until the property has been exhausted, when the information is naturally valueless. Hence the question becomes one of probabilities, never one of actually ascertained figures, and must always be considered as subject to the laws of probability in the mathematical sense. The quantity thus estimated divided by the estimated or proposed annual output determines the probable life of the property; if the latter is held under mineral lease, the period of which is less than the probable life, the length of the lease is substituted for the probable life in the calculations.

Sometimes not only the tonnage but also the assay value of the mineral deposit enters into the calculation, and in either case it is never a certainly known figure, but always the most probable figure, that has to be employed. Thus, where the value of a mineral deposit depends upon its thickness and its assay value, let the ascertained most probable thickness be T units and the ascertained most probable value be V units; as neither are known with certainty, these figures should be written $T \pm t$ and $V \pm v$ respectively, where t and v are the respective probable errors; then since the probable error of the product VT is $\sqrt{T^2v^2 + V^2t^2}$, the value of the deposit will be a function of $VT \pm \sqrt{T^2v^2 + V^2t^2}$. (See *Mineral Valuation*, by H. Louis, p. 128.)

In the following formulas, the annual income = annual tonnage × royalty per ton, or annual tonnage × profit per ton, as the case may be, will be designated by a.

The number of years of life of the property or of the lease will be designated by n.

The problem then becomes that of determining in the first instance the present value (P) of a series of annuities of £ a for a term of n years.

Generally the ordinary compound interest formulas apply, which show that X pounds invested at a rate of interest i per unit will amount in n years to $X(1+i)^n$, and conversely the present value of Y pounds payable at the end of n years, allowing interest at rate i, is

$$\frac{Y}{(1+i)^n}.$$

The main difficulty in all mineral valuations lies in determining the proper rate of interest to allow. The rate of interest in operations in which there is practically no risk, that is to say where the probability of the payment of capital and interest in full is practically unity, may be taken to be the rate obtainable by investment in such securities as Trustee Stocks. In all mining operations the risk is always greater, or in other words the probability of payment is less, hence a higher rate of interest is demanded to cover the risk. If i be the safe rate of interest the risk rate may be expressed by ri, where r is a number greater than unity, depending upon the conditions of the case, and which may conveniently be described as the risk factor; it may also be defined as the reciprocal of the fraction representing the probability of success, and is therefore greater the more hazardous the nature of the enterprise. In practice the risk factor ranges from 2 to 5, being lowest in well-proved bedded deposits, the uniformity of which has been determined by experience, and highest in veins or masses in which values are known to be very irregularly distributed. It is less where money is invested merely in the purchase of a mineral property than when it is invested in a mining enterprise, because royalties form a first charge on revenue and are almost invariably secured on the assets of the mining enterprise, whereas the latter can take only remainder profits, which are totally unsecured.

The determination of a proper risk factor is the principal problem that the mining engineer has to solve in valuations.

Present Value.

Let $ri = s$, so that s is the rate of interest *per unit* that is required in any given case.

Some writers call i the 'accumulative' and s the 'remunerative' rate of interest; the term 'risk rate' will be adhered to here in order to emphasise that the high rate is required in compensation for the risk that the investor runs. Of course i is governed by the money market, and is the rate of interest paid on investments in. Government stocks and similar first-class securities; it will be noted that s varies directly with i.

The value of the mineral property or mine *at the moment of commencing profitable operations* is therefore P, the present value of n annuities of £ a. This should obviously be equal to the present value of sums of £ a payable at the end of each of the first, second, third, etc., years up to the end of the nth year, and this sum

$$=\frac{a}{s}\left(1-\frac{1}{(1+s)^n}\right).$$

It is sometimes useful to remember that, if A is the present value of £ a due at the end of n years,

$$P=\frac{a-A}{s}.$$

The expression for present value given above is often spoken of as Inwood's formula. Calculations are easily made by this formula.

There is yet another method of looking at the problem. The annuity exceeds the simple interest on the present value by an amount equal to $a - Ps$ in each year; if this difference be allowed to accumulate at rate s for n years it will amount to

$$\frac{a}{s}\cdot\frac{(1+s)^n-1}{(1+s)^n}=P,$$

that is to say, to the original capital, as it obviously should do, because the purchaser of an annuity, spending each year only the interest on the capital invested, should get back his capital at the end of the period, because this operation would be equivalent to investing the capital at the given rate of interest during the given term of years.

This last method of looking at annuities has given rise to another method of calculating them, known from its originator as Hoskold's method. He considers that the risk rate of interest s should be allowed upon the capital, but that the difference between the annuity and the interest $(a-Ps)$ should be looked upon as accumulating at a safe rate i because it is not necessarily invested in the risky mining operation. This view gives rise to the formula

$$P=\frac{a}{\frac{i}{(1+i)^n-1}+s}.$$

This value may be taken out from any ordinary tables as follows :—

$$\frac{(1+i)^n-1}{i}$$

is the amount of £1 at interest i for n years, and the reciprocal

$$\frac{i}{(1+i)^n-1}$$

is the sinking fund for the repayment of £1, *i.e.* the sum to be set aside annually and allowed to accumulate at interest i in order to amount to £1 in n years. These values are obtained from tables. The denominator of the fraction in Hoskold's formula can be taken out by adding the risk rate to the sinking fund for £1 at interest i for n years.

This method is often used, but is not one that fairly answers all the tests of a true annuity formula. Nevertheless, it is used by valuers on the grounds that the difference between the annuity and the simple interest cannot, in fact, be invested at the risk rate s, but must be invested at the safe rate i, and that this method, therefore, more correctly represents what would obtain in actual practice.

Hoskold's method depends upon considering only one out of the various methods in which the true annuity formula may be looked at; obviously the two can be made to give the same result by selecting suitable risk factors in each case. Thus if r is the risk factor in Inwood's formula, and r' in Hoskold's method, the present values will be the same whichever formula be used, when

$$r' = \frac{r(1+ri)^n}{(1+ri)^n-1} - \frac{1}{(1+i)^n-1}.$$

It follows that r' must be greater than r; in other words Hoskold's method allows a rate of interest higher than the stipulated risk rate, and hence puts a lower present value on a given annuity. It need hardly be said that both his method and the ordinary method provide equally for the replacement of the original capital, if suitable sums are set aside in each case out of the annuities received.

Hoskold's is the generally accepted method of dealing with mineral valuation; it is, however, obvious that year by year a portion of the original purchase price (or present value) is withdrawn from the speculative investment and set aside to form the sinking fund for its repayment, whilst the risk rate of interest is still being paid upon the whole of the original purchase price. It might, however, fairly be stipulated that this risk rate is only to be paid upon such portion of the original capital as has not yet been redeemed by the sinking fund, which accumulates as before at the rate i per unit, whilst the portion of the capital thus withdrawn from the risky investment, though not yet really returned to the inventor is credited with interest at the rate j per unit (of course i and j may in some cases be the same). On the basis of these stipulations, the following formula results :—

$$P = a\,\frac{(1+s-j)^n-(1+i)^n}{s-(j+i)+s[(1+s-j)^n-(1+i)^n]}$$

(*H. Louis*, '*Trans. Inst. Min. Eng*,' lxx., 1925, p. 368.)

Since an investor in mines usually stipulates that he shall receive the risk rate of interest on his investment throughout the whole life of the mine, the Hoskold formula, though possibly less equitable, is generally applicable.

Increasing and Decreasing Values.

The above methods of valuing mineral properties tacitly assume that the mine will forthwith commence to produce at its full rate of output and will continue to do so until the mineral is worked out; this is, of course, not the case in practice, a mine only reaching its full output after several years, and this gradually declining again as the deposit approaches exhaustion. There would be no difficulty in allowing for this in the valuation, but as a rule it is neglected; as has already been pointed out, the figures on which the valuation is based are only probable, not actual figures, so that there is no use in endeavouring to attain minute accuracy in these computations.

There is obviously no difficulty in introducing these refinements if it is considered desirable; the computation is made as above for the estimated period of full production deferred during the period of production at a lower rate than the full output; the income expected in each year of output less than full output is calculated and its present value is determined, and all these present values are added together to obtain the total present value of the property.

The author has recently pointed out that this formula demands a risk rate also on the portion of the capital no longer at risk, and suggests the following :—

$$P = a\,\frac{(1+s-i)^n-(1+i)^n}{s-2i+s[(1+s-i)^n-(1+i)^n]}.$$

(See *Trans. Inst. M.E.*, *loc. cit.*)

If preferred, calculations can also be made directly, whether the annuity increase or decrease in arithmetical or in geometrical ratio. Let c be the income in the first year and let it increase or decrease by b each year, so that the income for the second year is $c \pm b$, for the third year $c \pm 2b$, etc., during n years. Then the present value of this annuity on the Inwood method is :—

$$c\left(\frac{(1+s)^n-1}{(1+s)^n s}\right) \pm \frac{b}{s}\left(\frac{(1+s)^{n-1}-1}{(1+s)^{n-1}s}\right) \mp \left(\frac{(n-1)b}{s} \cdot \frac{1}{(1+s)^n}\right).$$

These values can be taken out from the tables : the first expression is, as before, the present value of £c for n years at rate s ; the second is the present value of £$\frac{b}{s}$ for $(n-1)$ years at rate s, and the third is the principal which will amount to £$\frac{(n-1)b}{s}$ in n years at rate s.

If Hoskold's method be used, the present value is :—

$$\frac{c+\frac{b}{i}}{\frac{i}{(1+i)^n-1}+s} \mp \frac{nb}{i-s+s(1+i)^n}.$$

The first part of this expression is the present value of an annuity of £$\left(c+\frac{b}{i}\right)$ calculated for n years by Hoskold's method ; in the second expression $s(1+i)^n$ is the amount of £s at interest i for n years.

Again, let c be the income for the first year and let it increase geometrically by a ratio k, so that the income for the second year is ck, for the third ck^2 . . . etc., during n years. Then the present value of the annuity on Inwood's method is

$$\frac{c}{(1+i)^n} \cdot \frac{k^n-(1+i)}{k-(1+i)}, \text{ or, if } \frac{k}{1+i} = f, \text{ it is } \frac{c}{1+i} \cdot \frac{f^n-1}{f-1}.$$

On Hoskold's method the present value becomes :

$$c \cdot \frac{(1+i)^n-k}{1+i-k} \cdot \frac{i}{i+s[(1+i)^n-1]}.$$

All the above calculations are based upon the hypothesis that the annuity is paid at the end of each year ; in practice royalties are mostly paid quarterly, and mining dividends at least half-yearly. To meet this point, for n substitute $2n$, and for s substitute $\frac{s}{2}$ when payments are made half-yearly, these becoming $4n$ and $\frac{s}{4}$ respectively when payments are made quarterly.

Dead-rent.

In computing the present value of mineral royalties 'certain rent' or 'dead-rent' has sometimes to be taken into account. Mineral leases usually stipulate for a definite dead-rent, which may be in addition to the variable royalty, or may be a merging dead-rent, that is to say that the amount of royalty to be paid is determined by the tonnage which is in excess of that which corresponds to the dead-rent at the agreed royalty rate. As the dead-rent is payable in full, whatever the results of the mining operations, its present value must be calculated not on the mining risk rate of interest, but on a rate obtained by multiplying the standard safe rate by a factor depending only on the financial stability of the lessee. This consideration may be neglected when the dead-rent is very small compared with the expected annual royalty, but must be taken into account when it is considerable, the present value of the whole royalty, in the case of an additive dead-rent, or of the excess of royalty, in the case of a merging dead-rent, being computed as above and added to the present value of the dead-rent.

Relinquishment.

When, as is often the case, the lessee has power to relinquish the lease after a given number of years or at stated intervals, there is a risk that the lease may be cancelled because the mine proves unprofitable or because the deposit is exhausted, and the rate of interest applicable to the dead-rent during the definitely fixed period is estimated as above, but it must be multiplied by a risk factor representing the probability of such relinquishment in computing the present value of the dead-rent during the successive periods. Here, again, the difficulty of the problem consists entirely in determining the proper probability factor.

Deferment.

In opening a mine there is always a period of development during which no mineral is produced, or at any rate none is produced profitably, whilst the main capital expenditure in the way of shafts, adits, plant, machinery, etc., is incurred. The present value at the commencement of the profit-producing period as found above must therefore be looked upon as deferred for the requisite number of years and the actual value determined. If V be the actual value at the commencement of mining operations and d the number of years occupied in development,

$$V = \frac{P}{(1+s)^d}.$$

The risk rate of interest must be taken, because the capital is being spent and is subject to the full risks of the mining operation.

The annuity formula and deferred value formula may be combined, thus :—

$$V = \frac{a}{s} \cdot \frac{(1+s)^n - 1}{(1+s)^{(n+d)}}.$$

It is, however, better as a rule to make the computation in the two stages, as above.

Mr. O'Donahue has proposed a method of calculating deferments that has some analogy with Hoskold's method of computing the present values of annuities, being also a two-rate method. He considers that simple interest at the risk rate s should be allowed on the actual value V, whilst the interest assumed to fall due accumulates at the safe rate i, whence

$$V = \frac{P}{1 + \frac{s}{i}\left[(1+i)^d - 1\right]}.$$

Since interest is never in fact paid nor payable on the actual value, this method cannot be recommended. This formula and the ordinary deferment formula may be connected as follows :— Let r be the risk factor in the ordinary method and r' the risk factor when O'Donahue's method of deferment is employed ; then

$$r' = \frac{(1+ir)^d - 1}{(1+i)^d - 1} \text{ and } r = \frac{\sqrt[d]{1 + r'[(1+i)^d - 1]} - 1}{i}.$$

In some cases, however, where two different rates are involved, another method must be adopted. In the most general case, it is required to determine the present value, V, of a mine that will take d years to develop, during which time no profits are earned, and which will then yield a profit of a per annum during n years, it being a condition that the original capital shall bear interest at the risk rate s, but that all accumulations can only be invested at the ordinary investment rate i. At the end of the n years the investor is entitled to receive back his capital plus the accumulations of interest (Vs per annum) at the rate i or

$$V + Vs\,\frac{(1+i)^{n+d} - 1}{i}.$$

This must be equal to the amount of an annuity of a per annum for n years, or

$$\frac{a}{i}\left[(1+i)^n - 1\right].$$

Equating :—

$$V = \frac{a\left[(1+i)^n - 1\right]}{i + s\left[(1+i)^{n+d} - 1\right]}$$

This is the same result as follows from the method of calculating deferred annuities, published by Mr. George King in his 'Theory of Finance.' Further, if $d = 0$, the above formula becomes the ordinary Hoskold formula given above.

Capital Expenditure.

From the present value, V, as determined by any of the above methods, the capital necessary to bring the mine into full work must be deducted in order to obtain the value of the mineral property ; if the capital expenditure is spread over several years, the present value of this deferred expenditure must be computed at the ordinary investment rate i, and the sum thus found deducted from V.

DEFERRED DEVELOPMENT.

It occasionally happens that the valuation is required of a mineral property which it is not intended to commence to develop for a number of years; in this case the present value must be calculated as the present value of a sum V, the payment of which is deferred for the given period at a rate of interest *i* per unit. The risk rate of interest must not be taken into account, because there is no mining and therefore no mining risk. If the value of V has been properly determined, making all due allowance for mining risks, the problem resolves itself into determining what capital sum must be invested in safe securities in order to produce the sum V at the time when mining operations are to be commenced. Special attention is drawn to this point, because mistakes are often made in confusing the rate of interest required during the development period and the rate required during the period preceding development, the latter depending on ordinary actuarial considerations and not on the risks incidental to mining.

Investment Value.

Finally, in comparing investments in mines or in mineral properties with other investments of capital, the effect of Income Tax as well as of Mineral Rights Duties must be taken into account. Mines and minerals both constitute wasting assets, but income tax is charged upon the gross revenue derived therefrom, hence not only on the true revenue, but also on that portion of the gross revenue that ought to be looked upon as forming a sinking fund set aside to replace the original capital at the end of operations; mineral rights duties specifically affect only mineral properties and thus constitute an additional charge upon these. In both these respects, therefore, these investments are at a disadvantage compared with ordinary investments, a fact that requires due consideration in computing mineral valuations as a basis for the investment of capital.

ADDENDUM.

Income Tax.

It should be borne in mind in making annuity calculations that capital can only accumulate at the gilt-edged rate *i* less income tax. Thus the accumulative rate when the gilt-edged rate is 4½ % and income tax is 4*s.* 6*d.* in the £ is 3.4875 %. When there are no tables in existence corresponding to such rates, all calculations should be made by logarithms.

Cardox.

Cardox.—This is an explosive of quite a different type; it consists of a steel shell filled with liquid carbonic acid, which is converted into gas by the action of the heat of a mercury fuse, thus generating great pressure. The steel shell is blown out of the shot-hole and can be re-charged. (*Trans. Inst. Min. Eng.*, vol. cxxxi, 1931, p. 9.)

FURNACES.

CLASSIFICATION OF FURNACES.

FURNACES IN WHICH THE CHARGE AND THE FUEL ARE INTERMINGLED.

1. Hearth Furnaces.

(*a*) With blast. Forge for smithing. Grate for zinc-white manufacture.

(*b*) Without blast. Heap and stall for coking and roasting. Trough for liquation and drossing.

2. Shaft Furnaces.

(*a*) With forced draught. Blast furnaces for smelting ores of iron, copper, lead, etc. Cupolas for iron-foundry practice.

(*b*) With induced draught. Only rarely employed.

(*c*) With natural draught. Furnaces for smelting readily fusible ores. Kilns for calcining, roasting, etc.

FURNACES IN WHICH THE CHARGE AND THE FUEL ARE SEPARATE.

1. Reverberatory Furnaces (Radiation).

(*a*) With forced draught. Furnaces for the refining of metals and the smelting of ores.

(*b*) With natural draught. Furnaces for the roasting of ores. Furnaces for the manufacture of wrought iron, etc.

2. Crucible, Retort, Muffle, etc., Furnaces (Conduction).

(*a*) With solid, liquid or gaseous fuel.

(*b*) With electricity.

FURNACES IN WHICH THE CHARGE SUPPLIES ITS OWN FUEL.

(*a*) Preheated furnaces with solid charge. Kilns for ore-roasting. Beehive coke ovens.

(*b*) Preheated furnaces with liquid charge. Converters for refining, etc.

(*c*) Non-preheated furnaces with solid fuel. Blast-roasting furnaces with up and down draught.

ELECTRIC FURNACES HEATED BY RESISTANCE EFFECTS

(*a*) The charge is included in the electric circuit. Héroult aluminium furnace. Kjellin induction furnace.

(*b*) The charge is heated by means of an electrically-heated conductor.

ELECTRIC FURNACES HEATED BY ARC EFFECTS.

(*a*) Direct heating. The charge forms one or both poles of an electric arc.

(*b*) Indirect heating. The charge is enclosed in a space heated by an electric arc.

ELECTRIC FURNACES HEATED BY COMBINED RESISTANCE AND ARC EFFECTS.

Girod, Greaves-Etchells, Héroult, etc., steel furnaces.

SHAFT FURNACES.

BLAST FURNACES.

(Contributed by Colin Livingston.)

A blast furnace should be designed to suit the materials used in smelting; successful designs can best be accomplished by keeping in view the best practice with particular materials. No general formula for the design of all blast furnaces, for a given output, is possible. The following points are common to all successful blast furnace plants, and should be kept in view, in new construction:—

The aim of all blast-furnace work is the production of a good marketable iron at the lowest cost. Low costs rest chiefly on low fuel consumption; low fuel consumption is governed by the quantity of fuel, dryness and temperature of blast, with correct furnace lines for the ores smelted.

Blast temperature is entirely one of stove capacity; it is essential that stove capacity should be on the generous side.

Output will depend on capacity of furnace, diameter of hearth, and will vary according to materials used, quantity and pressure of blast, dry or wet blast, temperature of blast; blast pressure should be able easily to penetrate to centre of furnace.

Bosh line angles are found to vary very little; short steep bosh lines are a decided advantage with most materials. Leading American blast-furnacemen attribute some of their remarkable results, in part, to low steep boshes and large hearths.

Furnaces with hearths 20′ 9″ in diameter are in successful operation.

In general practice, furnace shafts should have a batter of at least 0·625 in. in 12 ins.; where fine ores are smelted this could be considerably increased with advantage. Diameter of bell should be 4 ft. to 4 ft. 6 ins. smaller than diameter of throat.

The furnace should be entirely enclosed in a strong steel shell, from the hearth level up.

All parts of furnace top work should be securely fixed to main shell structure.

In designing blast-furnace details the main considerations should be (1) efficiency, (2) strength, (3) simplicity.

The number of gas offtakes should be such that the gas leaves furnace as slowly as possible, so as to avoid carrying dust over to flues.

The height of furnace varies from 80 to 100 feet; with the materials used, each district has come to fix the height found most suitable for its particular conditions.

Sufficient relief area, by bleeders or explosion doors, should be provided on top of furnace to prevent injury from slips; the relief should, if possible, be directly upwards.

For hearth well and boshing nothing but the best quality of fire-brick should be used. The bricks should not be too large, so that they may be thoroughly burned.

For the upper lining a fire-brick with more wear resisting qualities can be used.

Care should be taken that all bricks when laid are properly bedded and tight built, with fire-clay joints as thin as possible.

In relining a furnace, the bear in old hearth need not be removed, but simply levelled to start building well on.

This will save much hard work and expense—experience will prove that nothing better for a hearth can be put in.

Some means should be taken to preserve the upper lines of furnace from wear where stock from bell strikes brickwork; a satisfactory way of doing this is to insert with brickwork alternate layers of cast iron or steel plates. In normal working, the stock level should be kept just high enough to allow bell to swing freely when full open.

The number of tuyeres is not so important (if sufficient area for output is provided) as equal distribution and penetrative power of blast.

There should always be a reserve of blowing power available after providing for normal maximum requirements.

Where blast-furnace gas is fully utilised and gas economy a necessity, the blowing should be done by gas engines. Where there is a surplus of gas the turbo-blower can be installed with advantage, and will prove an ideal blowing engine. Reciprocating steam-blowing engines are still being installed, but only in cases where conditions make it unsuitable or inconvenient to discard existing plant.

Cooling.—Apart from tuyeres, jumbos, and hearthcooling, any cooling appliances provided for the bosh or upper lining should be carefully considered; external or spray-cooling has the great advantage that leakage of water into the furnace is prevented, or rather more easily detected. The trouble caused by water leakage from blocks inserted in the building is considerable, and can never be fully known; it is often when the damage is done the leak is located. The latest practice is to spray-cool the bosh and sometimes the entire outside shell; by this means a much thinner brickwork can be used, the furnace preserves its original lines longer, and the lining has a longer life.

Stoves.—Should be as simple in design and equipment as possible, with ample facilities for cleaning and inspection, and have a good chimney draught.

Using unwashed gas, chequers should not have less than 9-in. by 9-in. openings; with washed gas smaller chequer openings can be used, giving greatly increased heating surface for same size of shell, and higher blast temperatures and lower chimney temperatures for same gas consumption. Openings 3½ ins. × 3½ ins. with 2-in. thick walls have proved satisfactory in practice.

In latest practice for heating stoves the gas and air is forced by special fan into combustion chamber, the stove burns more gas, which gives higher and more regular temperatures, with a saving up to 25 per cent. in stove construction for a given production.

Preheating the blast before entering the stove proper is in successful operation with increased average temperatures.

It is decided economy to clean blast-furnace gas, as better results are obtained.

It is no advantage to go beyond 1,550° F. in stove heats, any fuel economy being more than off-set by stove repairs.

Better results with certain ores will sometimes be obtained by running on lower blast heats; this may seem to conflict with theory, but in blast-furnace work it is often the case that sound theory follows successful practice.

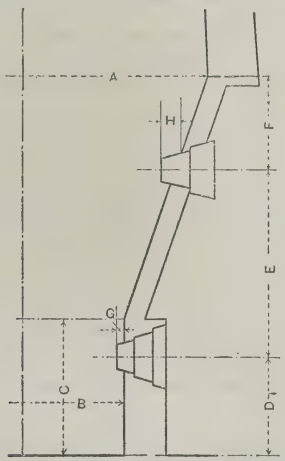

FIG. 1—Bosh Tuyere.

Uniform ore mixtures and quality of fuel and flux should be kept in view, rather than frequent changes of ore mixture, with varying qualities of fuel and flux. It is an advantage to break hard dense ores, especially magnetites.

The approximate saving in lbs. of coke per ton of iron by increase in blast temperature is as follows:—

1,000°	to	1,100° F.,	50 lbs.
1,100°	„	1,200° „	40 „
1,200°	„	1,300° „	30 „
1,300°	„	1,400° „	20 „

Dry Blast.—Average results with dry blast give a saving of 10 per cent. in fuel consumption with 10 per cent. increase in output, more regular grade of metal, and more regular working conditions.

A blast furnace in its working and results responds readily to improper treatment; proper regulation of flux has much to do with this, and the formation of a correct slag is all important.

The slag should not be too basic or limey; this causes the furnace to become stocky and gob up. If the slag is too acid the furnace will drive harder, but trouble is sure to result with grade and quality of pig.

When the lime content of slag is high it will prove profitable to make such slag into cement; the slag form from furnaces making Bessemer iron will generally be found suitable for this purpose. Most blast-furnace slags can be easily made into first-class building bricks.

The slightest indication of irregular furnace working should be promptly attended to and put right; irregular conditions will probably show first in change of slag or irregular settling of stock. The appearance and degree of fluidity of the slag is the furnaceman's best indication of working conditions.

Irregular working at tuyeres is generally caused by water leakage from jumbos and tuyere blocks. It is quite possible for tuyeres to be shut by water leakage, in spite of very careful watching.

No tuyere in a regular working furnace will close while the blast is on except by water leakage.

Irregular working at tuyeres is sometimes caused by an alteration in burden; in this case every tuyere will give trouble, which will continue till the trouble has been put right.

The best way to open tuyeres that may have been hard closed by slips, irregular working, or water leakage, is by the application of oxygen; the apparatus used is simple and cheap: the worst stuck tuyere can be opened in a few minutes.

Bosh tuyeres, it is claimed, increase the output of a furnace 20 per cent. with a slight increase in fuel consumption and more regular working. Fig. 1 and the 'Table of Bosh Tuyeres' give sizes and position of bosh tuyeres from actual practice.

TABLE OF BOSH TUYERES.

FLUE DUST.

The treatment of flue dust has developed into a distinct branch of blast furnace work; the true solution of the problem is to keep the dust in the furnace, thereby increasing production and reducing costs. Flue dust is caused chiefly by (1) fine ores; (2) soft fuel; (3) hard driving; briquetting or sintering gets over the first, but furnace design will need to be adapted to surmount the second and third.

For a comprehensive schedule of blast-furnace data see ENGINEER'S YEAR-BOOK, 1927, pp. 2580–2591.

CUPOLAS.

BLAST-QUANTITY AND PRESSURE IN CUPOLA WORKING.

An average of 120—in terms of quantity of air in pounds, multiplied by $\sqrt{}$ pressure in ounces is required to melt one ton of ordinary phosphoric iron.

The maximum output of metal melted per hour is more nearly comparative to diameters of cupolas than areas of same.

The maximum output of a cupola will be obtained when the pressure and quantity of the blast in ounces and pounds per minute respectively are so adjusted that $\frac{W\sqrt{P}}{D} = 330$, D being the diameter of the melting zone in feet. Any further increase in the product $W\sqrt{P}$ results in excessive oxidation of the metal in the cupola.

Iron melted in a cupola is affected in hardness directly as the pressure of blast used, so that the total area of the tuyeres employed should be regulated according to the class of iron being melted, small areas being used when greater hardness is required.

The height of the cupola from the top tuyeres to the charging-door sill should *not be less* than two and a half to three times the diameter across the melting zone.

The coke consumption in a well-designed cupola need not be more than 0·10 lb. per pound of ordinary phosphoric iron melted, when the coke contains from 90 to 92 per cent. of carbon.

Centrifugal Fans for Cupolas and Smith's Fires.

To give the high pressure required to supply air to Cupolas and Smith's Fires the fans must be of the 'centrifugal' type and suitably designed. They usually have smaller inlets and outlets than those used for ventilating, as pressure, not volume, is the essential feature.

Care is required in the choice of a suitable fan, as the efficiency varies within wide limits with the design.

Centrifugal Fans for Cupolas, Smith's Fires, etc.

No. of Fan.	For Cupolas.				For Smith's Fires.		
	Dia. of Cupola.	Tons per Hour.	Speed r.p.m.	Power B.H.P.	No. of Tuyeres.	Speed r.p.m.	Power B.H.P.
1	—	—	—	—	3	3,825	$\frac{3}{4}$
2	18	1	4,100	$2\frac{3}{4}$	6	3,050	$1\frac{1}{2}$
3	18	$1\frac{1}{2}$	3,150	4	10	2,440	$2\frac{1}{2}$
4	24	$2\frac{1}{2}$	2,950	7	15	2,280	$4\frac{1}{2}$
5	36	$3\frac{1}{2}$	2,600	10	20	2,030	$6\frac{1}{2}$
6	42	$4\frac{1}{2}$	2,230	14	28	1,810	10
7	48	6	2,050	20	37	1,510	13
8	54	8	1,800	26	50	1,400	18
9	60	10	1,600	35	60	1,250	24
10	66	13	1,450	42	80	1,080	32

The duct to the cupola or fires should be made at least as large as the fan outlet; in long lengths it should be made larger, so as to reduce friction, which increases the power to no purpose.

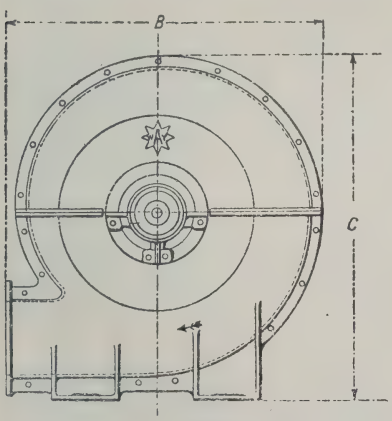

Fig. 2.

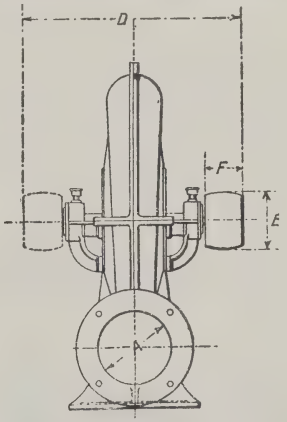

Fig. 3.

If the ducts are below ground cast iron is the best material; sheet-steel ducts $\frac{1}{8}$ in. thick, with flanged joints, are also very suitable, especially if carried above ground. If earthenware pipes are used great care must be taken to lay them straight, with good, sound, and permanent joints.

(*Sturtevant.*)

FORGE AIR PRESSURE.

The air pressure for a forge commonly varies from 2 to 4 ozs. per square inch, with an average of about 3 ozs. A pressure of 4 ozs. at the blower has been recommended when the average number of fires does not exceed ten, and a pressure of 5 ozs. when the number is more than twelve. Small forges with the blower close to them are adequately supplied with 1½ ozs. pressure. If the blower is some distance away and a long discharge pipe with many bends leads to the forge, even though the latter be small, it may be necessary to carry 3 ozs. pressure or more, to overcome the friction in the air ducts. The volume of free air required by the average forge fire is about 140 cubic feet per minute. The exhaust fan for a blacksmith shop should have a capacity approximately four times that of the forge blower, and should operate under a pressure of about ¾ oz.

REVERBERATORY FURNACES.

In a reverberatory furnace the material to be heated is contained in a long horizontal or slightly sloping hearth, the heat being supplied by flames and hot gases which travel over it. A considerable amount of heat is radiated on to the hearth from the arched roof of the furnace. The proportions of the various parts of the furnace are important, as if the roof is too high the gases will not 'lick' the hearth, but will travel close to the roof. Care must be taken to have a sufficient volume of gases in the furnace, as otherwise the upper part of the hearth will be too cool. There is a strong tendency to open the exit damper too wide. When in constant use, a reverberatory furnace heated by producer gas is more economical than one heated by solid fuel.

KILNS.

A kiln is a furnace which is filled almost completely with the articles to be heated. Usually the flames and hot gases from the fuel circulate among the goods and raise them to the required temperature by conduction. When contact with the kiln gases would spoil the goods, they may be enclosed in fireclay cases or a *muffle furnace* may be used.

MUFFLE FURNACES.

A muffle furnace is one in which the articles or materials to be heated are protected from direct contact with flames and hot gases from the fuel, but the term is sometimes used loosely for any kind of furnace heated by town's gas instead of solid fuel. The latter kind of furnace is extensively used for annealing, normalising, case-hardening, tempering, forging, and other heat treatments of iron, steel, and the non-ferrous metals.

The following are figures from actual practice :—

Operation.	Load.	Duration.	Cub. ft. ton.
Annealing H.S. steel . . .	3½ tons	8 hrs.	3,000
,, steel	3½ tons	15½ hrs.	6,000
,, C.I. parts packed in filings in boxes	2,000 lbs.	3 hrs.	3,360

CRUCIBLE MELTING FURNACES.

(L. C. Harvey.)

'Lift-out Crucible' or Pit Type Furnaces.—These are supplied where requirements of molten metal are small, or in cases where it is preferable to melt in relatively small capacity crucibles. *Natural Draught Coke Furnaces* can be either connected up to one main flue and chimney or can be provided with smaller collecting flues, each flue having a chimney to serve a small number of fires, or again, each fire can have its own small stack.

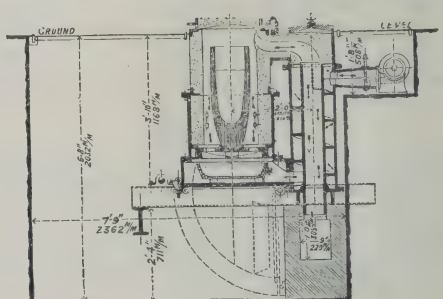

FIG. 4.—Furnace for Coke and Forced Draught. Sectional view, showing ground level.

Forced Draught Coke Furnaces (fig. 4) can be similarly arranged as regards provision for exhausting the waste gases, and as they are not dependent upon chimney pull the heights of stacks are considerably less than those required for natural draught furnaces.

It is usual to supply air from a blower or fan of sufficient capacity to feed any number up to the whole of the plant. Forced draught offers the advantages of (*a*) independence of atmospheric conditions, and, therefore, absence of variation in chimney pull; (*b*) quicker heating qualities of furnaces; (*c*) a greater degree of heat intensity than is possible under all conditions in natural draught furnaces.

Oil-fired Furnaces.—These can be fitted with burners to work with compressed air at 20-30 lbs. per square inch, depending to a large extent upon the temperature desired, the higher pressure effecting a more perfect atomisation of heavy grades of fuel, or with low pressure burners which run with a pressure of only ¾ lb. per square inch for all temperatures up to that necessary for melting mild steel and nickel.

The former require an air compressor, which is a relatively expensive machine, and may develop 5 to 10 h.p. per burner, whereas the latter needs only the ordinary open high-speed fan, and the burners will take 1½ to 2½ h.p. according to size of the furnace, etc. Almost any grade of commercial fuel oil can be used with either type of burner, and this is fed to the burners by gravity.

Producer Gas can be applied to lift-out crucible furnaces if these are made in the multiple form, viz. several crucibles in one common melting chamber, or several crucibles in separate chambers, but exhausting into one air or gas heating regenerator.

For ordinary low-power producer gas, 135 to 175 B. Th.U. per cubic foot, is essential to preheat the air or gas supply to about 300° C. for efficient melting of copper alloys; for iron and higher temperature melting, both the gas and air should be supplied at about this temperature.

When using high-power gas, such as water gas of roughly 280 B.Th.U. value per cubic foot no preheating is required for melting temperature up to about 1,400° C.

Tilting Furnaces *for Coke Fuel* are always of the forced draught pattern, for one of their chief features, quick heating, would be greatly impaired if worked on natural draught. This type of furnace is more efficient than the pit type, and it has the important advantage of melting in greater bulk than can be handled in a lift-out crucible—up to ½ ton of metal at one charge—and the further advantage of making it possible to mechanically tilt the furnace on a fixed front trunnion, so that the metal can be poured direct into ladles or moulds. In the portable pattern the body portion holding the crucible can be transported by means of an overhead crane to the point at which the molten metal is wanted.

Furnaces for Oil Fuel.—The remarks made above in connection with pit furnaces apply also to the tilting pattern. The economy in oil when melting, say, ½ ton of metal in one crucible with one burner, will be very marked, compared with, say, five burners for five 200-lb. size pit furnaces, and the consequent saving in power for air blowers in equal proportion.

Producer Gas can be applied to tilting furnaces as for pit furnaces, but tilting furnaces being of greater capacity than the latter it becomes possible to run single furnaces with producer gas, the heat in the waste gas being utilised to warm the incoming air or gas supply. For copper alloys it is usual only to preheat the air.

ELECTRIC FURNACES.

The classification of electric furnaces has already been dealt with (p. 2659). It remains to treat in detail of these furnaces and their application industrially.

Electric Furnaces Heated by Resistance Effects.

Those furnaces of this type in which the charge is included in the electric circuit (fig. 5) are of indirect interest only to the engineer. They are employed largely in the manufacture of aluminium, carborundum, calcium carbide, etc.

Those furnaces of this type in which the charge is heated by means of an electrically heated conductor find extensive employment in laboratories, and are coming into more general use for the annealing and thermal treatment of steel and the melting and heat treatment of non-ferrous alloys.

The smaller furnaces, such as are used in laboratories, are often made after the style of gas-heated muffle furnaces, but in place of gas jets, wire of platinum or incorrodible alloy, heated by the passage of an electric current, is wound round the body of the chamber. Another type consists of a tube of carbon, cut into a spiral or helix, through which the current flows.

Discussing furnaces of the larger type, T. F. Bally states that a 150-kW. annealing furnace heating 1,000 lbs. of steel to 900° C. in one hour consumes 300 kW.-hours per ton. With regard to melting in a shop working 24 hours per day, the following costs were recorded :—

	s.	d.
Electricity, 400 kW.-hours per ton at ½*d.* . . .	16	8
Metal loss, 1 per cent. zinc at 5*d.* per lb. . . .	8	4
Labour, 1 man per 600 lbs. per hour at ¼*d.* per hour .	5	0
Renewals and repairs	4	2
Total per ton of brass melted	£1 14	2

These furnaces are provided with separate heating elements of carbonaceous material, which do not come into contact with the charge, but are made incandescent by the current passing through them, and thus heat the interior of the furnace chamber.

Induction furnaces (figs. 6 and 7), which may be classed under this head, find employment in the manufacture of steel. They are able to hold their own against other types of steel-melting furnaces on account of their steady current consumption and low power consumption in the melting of cold stock, but suffer from certain disadvantages of a well-defined character. The heat being generated in the metal and only conducted to the slag, renders it impossible to work a fluid basic slag, with the result that desulphurisation of the charge is not so efficiently carried out as in the case of furnaces of the resistance or arc-resistance type. Nor can dephosphorisation be so perfectly attained, since the design of these furnaces militates against ready and complete removal of the oxidising slag needed for the removal of phosphorus. A further disadvantage arises as a result of the continuous circulation of the molten metal in the bath which leads to the erosion of the lining. This, in addition to the corrosive effect of the slag, leads to high figures for lining repairs.

Were the induction furnace of more flexible character and efficient design, it should find wide application in the melting of brass containing as high as 50 per cent. zinc. At present this type of furnace is being experimented with in the direction of non-ferrous alloy melting.

Electric Furnaces heated by Arc Effects.

Only furnaces in which indirect heating of the charge (fig. 8) is carried out are of interest in this connection. The Stassano furnace is the most striking example of this type. The power consumption of arc furnaces is high, and fluctuations in the value of this factor are, when the furnace is being employed in the fusion of cold stock, of high magnitude.

In the melting of copper alloys the indirect arc furnace may be employed economically in large units. It has also been used for melting brass containing not more than 10 per cent. zinc.

Electric Furnaces heated by Combined Resistance and Arc Effects.

By far the largest number of electric furnaces in use industrially are of this type. In this class of furnace an arc is struck between the extremities of vertical electrodes and the liquid or solid furnace charge (fig. 9). In many furnaces of this type negative electrodes are built into the furnace bottom or sides so that current is forced to flow through the bath (fig. 10). In both cases the bath is heated by (i) the heat of the arc and (ii) the heat produced by the resistance of the steel and slag to the passage of electric current.

The electrodes, which are of graphite or amorphous carbon, are capable of movement in a direction parallel to their axis and are controlled, either by hand or by electrical device, so as to retain the arc at as constant a length as may be desired either for melting, refining, heating, etc., of the metal. In certain cases the practice of completely immersing the electrode in the molten charge—thus utilising the resistance effect of the electric current only—is in vogue.

For making steel the arc resistance type of furnace is that chiefly used, the charge generally consisting of scrap steel. The composition of electric steel can be very accurately controlled, and the proportions of sulphur and phosphorus in the final product can be reduced to mere traces. These and similar furnaces are largely used for making small castings in steel, malleable iron, and cast iron, their capacities ranging from 1 to 20 tons ; 6-ton furnaces are very common. Other well-known furnaces of this class are the Girod, Nathusius, Keller, Gronwall, Electro-metals, and Greaves-Erchells. While steel melting and refining, and the production of steel and iron castings, occupy the vast majority of electric furnaces, all the foregoing types can be, and have been, used for melting brass, copper, etc., though it is questionable whether their use for such purposes can be considered as expedient.

Arc-resistance furnaces for steel melting are most frequently lined with basic refractory materials. Acid-lined furnaces are, however, employed, chiefly to melt down high-grade raw materials. The necessity for utilising such materials, for which high prices must be paid, renders the mere melting process a costly one. Further, as the treatment of molten steel on an acid hearth leads to an appreciable gain in those elements, sulphur and phosphorus, most to be avoided, the process is still further limited in its application.

The process employed for the production of steel in basic-lined arc-resistance furnaces is determined by (i) the stock on hand and (ii) the product desired.

Should the stock on hand be of fair quality, *i.e.* containing contents of sulphur and phosphorus not above 0·06 per cent., the process may consist of (i) the application to the charge of a basic oxidising slag and (ii) the conversion of this slag, by means of suitable additions of coal dust and lime, into a reducing slag, which is allowed to remain in contact with the molten steel during the operations of teeming from the furnace and of casting from the ladle. Such additions of ferro-alloys as are required to bring the steel up to the standard required are made when the slag is as completely reducing in character as is possible under the conditions imposed by practice.

If the stock on hand is of poor quality—*i.e.* scrap containing high (from 0·06 to 0·20 per cent.) sulphur and phosphorus—or if it is desired to specially refine stock of fair quality, the first slag—the basic oxidising slag—is removed from the surface of the steel in the furnace. The removal of this slag implies the removal of the major portion of the phosphorus from the steel, and unless the removal be very complete a return of phosphorus to the steel may be expected, the content of phosphorus returning to the steel under these conditions being roughly proportional to the amount of slag allowed to remain upon the charge. Occasionally it may be necessary to apply a further oxidising slag to the metal in the bath ; generally, however, one slag only is made. The first slag having been removed, deoxidation and desulphurisation are effected by the medium of a slag composed largely of calcium silicate. The 'physic' required to provide for carbon, manganese, etc., in the finished steel may be added immediately after the first slag has been removed. Generally speaking, the additions are made at a later stage in the process. The complete deoxidation of the metal is made evident by the appearance of the slag, which, the above conditions prevailing, decrepitates spontaneously and is practically white when cool.

Melting and refining carried out on a basic hearth results in a practically complete loss of carbon, silicon and manganese, and a very appreciable loss of sulphur, phosphorus and such elements as chromium, molybdenum, etc.

The possible uses of the electric furnace in the steel foundry have been tabulated by J. H. Hall :—

Melt scrap . . .	Impure : eliminate phosphorus and sulphur. Pure : get hot and cast. Alloy steels.
Melt pig and more or less scrap. Eliminate C, Si, Mn.	Impure : eliminate phosphorus and sulphur. Pure : get hot and cast.
Treat hot metal . . .	From cupola : eliminate C, Si, Mn, S and P. From acid Bessemer or open hearth : eliminate S and P. From basic open hearth : eliminate S and P.
Melt pig and scrap and treat cupola metal	Eliminate C, P and S without loss of Mn and Si. (Greene's process.)

The arc-resistance furnace proved to be of value during the war in the preparation of high-grade pig iron to replace the Swedish pig iron so much sought after for the preparation of high-grade steels.

According to E. K. Scott, a 10-cwt. steel-melting furnace running 9 charges a day will do as much as 36 crucible-steel furnace holes, each accommodating two 56-lb. pots, and can be operated by one man and an ammeter boy, whereas the crucible furnaces require 15 men, most of them skilled. The electric furnace, with its transformer and switch-gear, occupies one quarter as much space as the crucible plant, and costs half as much to instal. It can deal with a charge consisting entirely of turnings, millings, etc., whilst in the crucible-steel process only a very limited quantity of turnings can be used. The renewal of the furnace linings costs less than that of crucibles for the same output. Consequently the electric-steel furnace has in a number of cases been adopted in Sheffield in place of crucible furnaces.

The chief **losses** in electric furnaces are due to radiation from the walls and conduction through the electrodes. Since the radiation losses increase as the square and the capacity as the cube of the linear dimensions of furnaces, it is obvious that large installations are more economical than small ones. Conduction losses can be reduced to a minimum by suitably designing the electrodes.

Although, with coal at 14*s.* per ton and electrical energy at ½*d.* per kW.-hour, the latter costs twenty-eight times as much as the former per British thermal unit purchased, the efficiency with which the electrical energy is applied is so much higher that the difference is largely neutralised, and in the case of crucible steel is completely wiped out. In addition, the labour cost is greatly reduced with electric furnaces and there is a considerable economy of space and buildings, while the steel produced is of higher quality and uniformity than by any other method.

A useful method of calculating heat flow through the furnace walls, etc., has been developed by Carl Hering on the lines of Ohm's law. If—

W = heat flow in watts ; T = drop in temperature in degrees C. ; R = thermal resistance in 'thermal ohms,'

then,

$$W = T/R.$$

A thermal ohm is that thermal resistance which requires a drop of temperature of 1° C. to produce one watt of heat flow and = 4·2 gramme-calorie units ; 1 gramme-calorie unit of thermal resistance = 0·24 thermal ohm.

Assuming that the electrodes are of uniform section, and that no lateral loss of heat takes place—conditions which are only approximately fulfilled in practice—Hering finds that the total loss of heat through the cold end of the electrode equals the sum of the loss by heat conduction alone (*i.e.* when no current is flowing) and half the T^2R loss. This combined loss is least when the loss by heat conduction alone equals half the T^2R loss ; the total loss then equals the T^2R loss, and no heat will be conducted out of the furnace by the electrodes. This minimum loss is dependent only on the material of the electrodes, the current, and the temperature, but not on the absolute dimensions ; it fixes the ratio of cross-section of electrode to length. In the case of a furnace working at 1,400° C., the cool end of the electrode being at 100° C., the length of the electrode 20 ins., and the current 10,000 amperes, the following dimensions were given by Hering's method of calculation :—

Carbon, 12·5 ins. diameter, loss of power in electrode 23·4 kW. ; Graphite, 7·1 ins. diameter, loss of power 15·1 kW. ; Iron, 4·8 ins. diameter, loss of power 4·6 kW. (*Stansfield.*)

F. T. Snyder states that in the case of a furnace melting 1,000 tons of steel a month, the cost of renewing the electrodes, plus the cost of the heat conducted out of the furnace by them, represents an expenditure of some 1,200*l.* a year per electrode. Hence the type of furnace having the fewest electrodes has an advantage in this respect. By using the metal bath as one terminal of the arc, a furnace can be operated with one carbon electrode per arc. The furnace lining becomes conducting at very high temperatures, and this fact limits the voltage between two electrodes passing through the same roof to a maximum of 110 volts to avoid serious leakage of current. The bulk of the cost of renewing refractory linings is due to roof wear round the electrodes, and for the size of furnace above mentioned can be kept down to 800*l.* per annum per electrode. The higher the power input the quicker is the heating and the greater the efficiency of the furnace. With three electrodes the limit of power is soon reached, owing to lack of room to space the electrodes sufficiently far apart to prevent current leakage through the roof lining, but with a single electrode there is no such limit to the power input.

The power, etc., provided in connection with Héroult furnaces used by the United States Steel Corporation are given in the following table, which applies to cold charges ; if the charge is put into the furnace in a molten condition about half this power suffices :—

POWER REQUIRED FOR ELECTRIC FURNACES.

Size of Furnace, tons.	Transformer capacity, kVA.	Amperes, per phase.	Square inches Copper, per phase.
1	375	2,250	3
2	600	3,600	5
3	750	4,500	6
4	900	5,400	7
6	1,200	7,200	9
10	2,000	12,000	16
15	3,000	18,000	24

The voltage used in arc furnaces depends upon the current and the length of the arc. In three-phase furnaces it ranges between 75 and 100 volts, and in single-phase furnaces between 150 and 200 volts. In resistance furnaces the voltage at starting, with a cold charge, may be 400 volts, decreasing as the charge heats up to 35–60 volts. The consumption of the electrodes varies widely according to the conditions obtaining, from $3\frac{1}{2}$ to 20 lbs. per ton of steel produced. The furnace bottoms last from 1 to 3 years, the walls from 100 to 300 heats, and the roof from 50 to 200 heats. To make ordinary carbon steel of crucible quality with a 6-ton furnace requires from 550 to 750 kW.-hours per ton, starting cold. In smaller furnaces the input per ton is greater. The following figures for a Rennerfelt furnace are due to C. H. Vom Baur.

ENERGY REQUIRED IN TREATING VARIOUS METALS.

	kW.-hours
Melting red brass	168
„ pure copper	197
„ white iron	290
„ gray iron	325
„ 80 per cent. ferro-manganese	441
„ and refining steel scrap on a basic bottom	700

The power factor of the arc resistance furnace varies from 85 per cent. to more than 90 per cent. : that of the resistance type from 90 to 97 per cent. ; that of the induction furnace varies from 50 to 60 per cent. only.

The efficiency of a Héroult furnace was tested with a charge consisting of 5,733 lbs. steel scrap, 430 lbs. iron ore, 346 lbs. lime. The input was 215 kW. for the first hour, at 110 volts, and afterwards 342 kW. The total time taken to melt the charge was $5\frac{1}{4}$ hours, and the total energy input for melting was 1,680 kW.-hours. The ratio of heat utilised to heat supplied (the efficiency) was 76·5 per cent. The time required for the purification and carburisation of the steel was 3 hours, and the result was 5,161 lbs. of tool steel. The total consumption of energy was 2,580 kW.-hours, or 0·171 e.h.p.-year per ton of steel.

The leads from transformers to electric furnaces should be as short and direct as possible, and close together, as the voltage drop due to their self-inductance and the very large currents is considerable, resulting in a low power factor. The conductors should be wide thin bars, or tubes, to prevent loss of energy due to the tendency of alternating current to flow in the skin of the conductor.

ELECTRICAL RESISTIVITY OF MATERIALS, OHMS PER INCH CUBE.

Material.	Cold.	Hot.	Temperature ° C.
Graphite	0·00034	0·00031	100–2000
Carbon	0·0018	0·0014	100–2000
Silicate slag	∞	1 to 2	Molten
Fire bricks (various)	∞	8 to 24	850
		24 to 300	815

(*Stansfield.*)

FURNACE CONSTRUCTION.

The following are points requiring special attention in the construction of furnaces :—

1. Sections of furnaces such as are exposed to differing physical and chemical actions should be united in such a manner as to allow of free and independent movement and as to be subject to independent condition.

2. Such sections as are exposed to high temperatures should be made thin and should, when possible, be water-cooled; such sections as are exposed to low temperatures should be made of such a thickness as will reduce thermal losses due to radiation and conduction to a minimum.

3. The interiors of furnaces should be constructed so as to resist mechanical, physical and chemical wear. With this end in view choice must be made of suitable materials of construction and of efficient design. In this connection note should be made of the following factors :—

(*a*) The action of heat.

(*b*) The erosive and corrosive actions of flame, slag, etc.

(*c*) The mechanical wear due to abrasion by the solid charge, etc.

4. The exteriors of furnaces should be supported and strengthened in such a way as to allow of the free expansion and contraction of the body. The foundations of all furnaces must be of a strong and rigid character.

MELTING POINTS OF REFRACTORY MATERIALS.

	° C.
Alumina (pure)	2010†
Bauxite	1820†
Bauxite brick	1565 to 1785†
Bauxite clay	1795†
Chromite	2180†
Chromite brick	2050†
Fireclay brick—Highest grade	1843*
General grade	1650 (average)*
Ditto	1649 (average of 41 samples)†
Ganister	1700 to 1800
Kaolin	1735 to 1740†
Magnesia brick	2165
Silica—Pure	1750†
Pure	1830*
Pure, with 14·5 per cent. alumina	1690*
Pure, with 63·0 per cent. alumina	1890*
Brick	1700 to 1750†

The melting points have been considered to be those temperatures at which the material in question was first seen to flow easily.

FURNACE EFFICIENCY.

The thermal efficiency of furnaces may be stated either absolutely or relatively :—

$$\text{Absolute furnace efficiency} = \frac{\text{Net thermal effect produced}}{\text{Calorific power of the fuel}}$$

$$\text{Relative thermal efficiency} = \frac{\text{Net thermal effect produced}}{\text{Actual calories realised}}$$

Owing to the large variation in the actual number of calories realised in individual furnaces it is general to employ the former of the above ratios. In order that a determination of the absolute efficiency of a given furnace may be made, a knowledge of the heat-absorbing and the heat-producing factors that are likely to be encountered in practice, of which a number are tabulated below, is required.

(*A*) Heat-absorbing Factors.

1. Heat absorbed by fume, gases, etc.
2. Heat removed by such solids and liquids as are periodically or continuously removed from the furnace.
3. Heat lost by radiation and conduction.
4. Heat absorbed owing to endothermic reactions within the furnace.

(*B*) Heat-producing Factors.

1. Heat supplied to the furnace by the combustion of fuel either inside or outside the furnace.
2. Heat added by such solids and liquids as are periodically or continuously charged into the furnace.
3. Heat gained owing to exothermic reactions within the furnace.

The thermal efficiency of the furnace is represented by the ratio of the heat-absorbing factors to the heat-producing factors.

* Boudouard.

† Kanolt—'Iron and Coal Trades Review,' vol. lxxxv. p. 309.

Heat Economy by Insulation.

A considerable reduction in the loss of heat by radiation (see *A*, 3, above) may be effected by building a ' wall ' of insulating bricks (p. 435) between the lining and the exterior of the furnace.

Latent Heat of Fusion of Metals.

The latent heat of fusion is the number of gram calories required to convert one gram of substance from solid into liquid without change of temperature :—

Mercury	2·8 calories.	Platinum	27·1 calories.
Lead*	5·5 ,,	Sodium	31·7 ,,
Bismuth*	10·2 ,,	Palladium	36·3 ,,
Cadmium*	10·8 ,,	Manganese*	36·7 ,,
Tin*	13·8 ,,	Antimony*	38·9 ,,
Potassium	15·7 ,,	Copper	41·0 ,,
Gold*	15·9 ,,	Nickel*	56·1 ,,
Iron	(See note).	Cobalt*	58·2 ,,
Silver*	26·0 calories.	Aluminium*	94·0 ,,
Zinc*	23·0 ,,		

NOTE.—The latent heat of fusion of iron as determined by Campbell (and confirmed by Desch) from freezing-point depression data is 20·1. C. Brisker (1908), as a result of an examination of Carpenter and Keeling's freezing-point determinations of the iron-carbon system, has arrived at the value 31·6 for this element. Grumer gives values of 23 and 33 for gray and white cast iron respectively. Wüst obtained the value 49·4 for this factor.

Heat and Electrical Energy required for Fusion of Metals.

The following table (after Stansfield) gives the heat and electrical energy required to melt various metals, per lb. :—

	Calb.†	Watt-hours.		Calb.†	Watt-hours.
Tin	28	15	Copper	162	85
Lead	16	8	Cast iron (gray)	245	129
Zinc	68	36	Tool steel (1 % C.)	300	158
Aluminium	258	136	Wrought iron	343	181
Brass	130	69			

(See also p. 2671.)

TEMPERATURE CONTROL OF FURNACES—PYROMETRY.

Determination of Calorific Intensity.

The calorific intensity of a substance is the theoretical maximum temperature attained during the perfect combustion of the same in air at 0° C. and 760 mm. pressure, and is inversely proportional to the time occupied in attaining to this temperature. The calorific intensity of a substance may be determined by calculation or by experiment.

CALCULATION.

Let C = the calorific power of the substance,
T = the rise in temperature during combustion,
$w, w', w'', — $ = the weights of the products of combustion,
$s, s', s'', — $ = the specific heats of the products of combustion,

then,

$$T = \frac{C}{ws + w's' + w''s'' + \text{etc. etc.}}$$

for the fuel at 0° C. and 760 mm. pressure.

The calorific intensity of a fuel (by formula) will be seen to be directly proportional to the calorific power of the fuel and inversely proportional to the weights and the specific heats of the products of combustion.

The calorific power can be raised by

(*a*) Superheating the fuel.
(*b*) Superheating the air needed for the combustion of the fuel.
(*c*) Using a minimum of excess air.
(*d*) Increasing the proportion of oxygen in the air.
(*e*) Reducing the proportion of incombustible material in the fuel.

---

* Values after Wüst. *Stahl und Eisen*, 1918, 38, 177.

† *Calb.*—The amount of heat required to raise one pound of water through one degree Centigrade.

Calorie.—The amount of heat required to raise one gram of water through one degree Centigrade.

Expansion Type Thermometers.

The mercurial thermometer is most important for use at about atmospheric temperatures, largely on account of the wide range of temperatures through which mercury is liquid, —39° C. to 357° C. If a high-grade mercurial thermometer has been calibrated at the National Physical Laboratory, it is possible to measure temperatures throughout its range to an accuracy of 0·001° C By the use of inert gases (nitrogen or carbon dioxide) under pressure in the tube of a thermometer, the boiling point of the mercury may be raised to allow temperatures up to 540° C. to be determined, at which temperature the glass softens. Quartz thermometers containing mercury under pressure can be used up to 700° C. By using tin instead of mercury the maximum limit may be raised to 1000° C. Steel tube mercurial thermometers, in which the capillary is attached to a form of a Bourdon pressure gauge, are not easily broken, and may be relied upon up to 540° C.

Fusion Pyrometers.

Observations of the fusion of metals, alloys, salts or mixtures of salts enable the observer to judge the temperature reached in a furnace at the moment of fusion, given that the temperature of fusion of the material employed is known prior to its introduction into the furnace. Fusion pyrometers are most suitable for the registration of maximum temperatures, after the attainment of which the source of heat may be eliminated and the furnace or heated object allowed to cool.

Metals.

The base metals have the disadvantage of ready oxidation ; the precious metals offer only a limited number of definite temperatures.

Alloys.

Only eutectic alloys (see p. 2678) and solid solutions (see p. 2678) are of value. Base metal alloys being subject to oxidation, only precious metal alloys remain as suitable fusion pyrometers. Both the alloys of silver and gold and those of gold and platinum have been employed for pyrometric work, the latter, according to Séger, being satisfactory up to a temperature of 1200° C. only.

Salts.

The following are the melting points of a number of metallic salts that have found use in pyrometric work :—

Salt.	Melting Point.	
Calcium nitrate	561° C.	1042° F.
Strontium nitrate	570 ,,	1058 ,,
Barium nitrate	593 ,,	1099 ,,
Potassium iodide	705 ,,	1301 ,,
Potassium bromide	750 ,,	1382 ,,
Potassium chloride	790 ,,	1454 ,,
Sodium chloride	800 ,,	1472 ,,
Sodium carbonate	849 ,,	1560 ,,
Sodium sulphate	880 ,,	1616 ,,
Barium chloride	960 ,,	1760 ,,
Potassium sulphate	1050 ,,	1922 ,,

Mixtures of Salts.

Under this heading may be included two important types of fusion pyrometers :—

(*a*) Séger cones.

(*b*) Sentinel pyrometers.

Séger Cones.

These are small three-sided pyramids, each about 2½ ins. high and about ½ in. wide at the base. The term 'cone' is rather misleading, as they are more pyramidal than conical. They are made of a finely ground mixture of felspar, china clay, and flint, the composition of the mixture depending on the temperature to be indicated. For the lower members of the series other mixtures are used.

These cones were invented by the late Dr. Séger of Berlin, in order to provide some means of recording the effect of heat on various porcelains. Their shape and composition are such that when heated to their indicating temperature at a reasonably slow rate and under suitable conditions they bend over slowly from the upright position possessed by them when placed in the kiln or oven and gradually form an arch. When the top has almost reached the same level as the base the indicating temperature is reached. A further rise in temperature will cause the cone to collapse and form a shapeless, glazed mass.

It is customary to employ three different cones at a time ; the first will indicate a temperature about 20 degrees Cent. below the one required to be known, the second cone will indicate the desired temperature (such as the finishing temperature of a glaze) and the third cone will serve as an indicator that the required temperature has not been exceeded by 20 degrees. The composition of the cones is such that the difference in temperature shown between two successive cones is about 20 degrees, though they are not quite regular in this respect.

It is important to remember that Séger cones do not serve as strict indicators of temperature in the sense that a thermometer does. If heated too rapidly a much higher temperature may be reached than is normally required to bend a cone, and which they are supposed to indicate. Under ordinary conditions of use, however, it is easy to find which cones correspond to the temperatures or conditions of heating which it is required to control, and Séger cones are, therefore, invaluable when they are rightly used. They serve as excellent indicators of the effect of heat on pottery and similar materials, and as it is this, rather than the mere momentary temperature which is important, they have advantages not possessed by a pyrometer or high temperature thermometer.

They were originally made only at Dr. Séger's laboratory in Berlin, but since 1914 they have also been made at the Pottery School, Stoke-on-Trent, and sold by Messrs. Keeling & Walker, Sutherland Mills, Stoke-on-Trent.

Owing to their cheapness and the difficulty of ensuring their accuracy when made by amateurs it is usually better to purchase the cones rather than to attempt to make them.

The following temperatures are those nominally associated with Séger cones, but, as explained above, it is preferable to refer to the number of the cone rather than to the temperature.

SÉGER CONES AND TEMPERATURES.

Séger Cone.	Deg. Cent.	Deg. Fah.	Séger Cone.	Deg. Cent.	Deg. Fah.	Séger Cone.	Deg. Cent.	Deg. Fah.	Séger Cone.	Deg. Cent.	Deg. Fah.

SENTINEL PYROMETERS.

These are small cylinders, measuring about $\frac{1}{2}$ in. by $\frac{1}{2}$ in. and manufactured from salt mixtures of definite melting points. Only such mixtures can be utilised as are formed of salts that neither dissociate nor corrode when in the molten state. Brearley states that ' mixtures of salts, after being melted together and ground to a very fine powder, may be made into an adhesive paste with vaseline, and applied to many purposes for which no ordinary pyrometer is available. In the smith's hearth, for example, a tool may be heated to low redness and smeared near the point with a small portion of a paste whose melting point is, say, 770° C. The tool is then reheated directly in the fire or protected from the coke by a piece of scrap, wrought or cast iron piping, until the white mark left by the thin layer of the salt mixture disappears. This indicates that the steel itself has nearly reached the desired temperature and may be quenched.'

The following are the melting points of a number of mixtures of salts:—

Salt.	Parts by Weight.	Salt.	Parts by Weight.	Deg.
Potassium carbonate . .	50	Potassium chloride	50	580 C.
Sodium chloride . .	30	Ditto	70	625 C.
Ditto	42	Ditto	58	655 C.
Potassium sulphate .	20	Sodium sulphate	80	825 C.
Ditto	30	Ditto	70	830 C.
Ditto . . .	50	Ditto	50	850 C.

Heat Radiation Pyrometers.

In this type of instrument the relation between the effect of radiant heat on suitably chosen thermal elements and the temperature of the radiating body is observed. The Féry Radiation Pyrometer is an example of this class of instrument.

In this pyrometer the rays from the hot body are received on a concave mirror, which can so be adjusted that the rays form a heat image which covers a small sensitive element permanently fixed on a line through the axis of the mirror. The sensitive element consists of a delicately adjusted thermo-couple, which delivers current to a millivoltmeter, calibrated, if desired, to read the temperature of the body, whence the heat rays are emanating, directly. In both cases suitable means are provided for ensuring that the sensitive element is completely covered by the image of the radiant body.

In order that correct results may be obtained when using pyrometers of the radiation type it is necessary that the hot body sighted should be enclosed within a vessel whose walls are approximately at the same temperature as the body itself. If this precaution is not observed the reading obtained will be lower than the true temperature of the body, the degree of inaccuracy being dependent almost entirely on the nature of the surface of the body in question.

Optical Pyrometers.

Approximate estimations of the temperatures of incandescent bodies may be made by visua observation. Numerous colour scales have been proposed, but those due to Howe and Taylor and White are generally accepted as the most accurate. The following table (based on one by Howe) is of value in this connection.

Taylor and White.		Howe.	
Name of colour.	Degrees C.	Name of colour	Degrees C.
—	—	Lowest visible red in the dark	470
—	—	Lowest visible red in daylight	475
Dull red, blood red, low red	566	Dull red	550–625
Dark cherry red	635	—	—
Cherry, full red	746	Full cherry	700
Light red, bright cherry, light cherry	843	Light red	850
Orange	899	—	—
Light orange	941	—	—
Yellow	996	Full yellow	950-1000
Light yellow	1079	Light yellow	1050
White	1205	White	1150

The design of optical pyrometers is dependent on the fact that the intensity of the light rays emitted from an incandescent 'black body' is directly proportional to the temperature of the 'body.'

The Mésuré and Nouel Pyrometric Telescope consists of two suitably mounted Nicol prisms, so adjusted that their planes are at right angles to one another when the scale of the instrument is at zero and between which is placed a quartz plate cut perpendicularly to its axis. When the incandescent body is observed through the instrument it is necessary to rotate one of the Nicols in order to extinguish the emitted light. The angle of rotation is proportional to the thickness of the quartz plate, which is a constant for any given instrument, and inversely proportional to the square root of the wave length of the observed light. The wave length of the observed light being proportional to the intensity of the light, the angle of rotation of the analyser or polariser is a measure of the temperature of the incandescent body.

The Cornu-Le Chatelier Photometric Pyrometer is designed to measure the intensity of the light emitted by an incandescent body by reducing this intensity until it corresponds to that of the light emitted by a standard lamp. The reduction required is inversely proportional to the temperature of the hot body.

The Wanner Photometric Pyrometer likewise compares the intensities of the lights emitted by the incandescent body and a standard body respectively. In this instrument, however, spectra of the two sources of light are, firstly, broken up into two polarised planes at right angles to one another; secondly, adjusted so that only the narrow red bands of each spectrum are transmitted further; and, thirdly, so brought into vision that the intensity of either field, both being in visual contact, can be strengthened or weakened, until they are equally intense, by rotation of a Nicol prism. The amount of rotation, which can be observed on a suitably situated scale, serves to measure the intensity of the emitted light, and hence to define the required temperature.

The Cambridge Optical Pyrometer is, in principle, the same as the foregoing, and is invaluable for temperature measurements between 700° and 4000° C.

Thermo-Electric Pyrometers.

This type of pyrometer is dependent for its action upon the fact that a current is produced within a closed circuit formed of two dissimilar metals when the junction between the two metals is heated, the current being proportional to the absolute temperature of the junction.

The essential features of this pyrometer are two thin insulated rods or wires of dissimilar metals coupled at one of their ends and connected at their other ends to separate leads. The connection between the two metals and the leads, which is known as the ' cold-junction,' is enclosed within suitably designed apparatus that can be retained at a known constant temperature. The leads from the ' cold-junction ' pass to some form of electrical instrument capable of registering or recording changes in the P. D. produced in the now closed circuit when the thermo-couple is heated or cooled.

The number of metals and alloys available for the manufacture of thermo-couples are few. The following are among those most generally employed :—

Couple.	Range.
Platinum—platinum rhodium	Up to 1400° C.
Platinum—platinum iridium	„ 1000 „
Nickel—nickel chromium	„ 800 „
Silver constantan	„ 600 „
Copper constantan	„ 500 „
Iron constantan	„ 500 „

For the estimation of temperatures above the melting-point of platinum the iridium-iridium-ruthenium couple has been suggested, but it is considered unlikely that the same would prove efficient, on account of the known volatility of iridium at such temperatures.

Union between couple *wires* is effected by fusion in the electric arc or oxyhydrogen flame in the case of couples having a platinum base, by soldering or brazing in the case of base-metal couples or by twisting. Union between the wires and the leads can be effected as above or by means of electrical clamps.

The couple wires, when in use, are generally protected by tubes of nichrome, fireclay, silica or glazed porcelain, the last being particularly useful when it is desired to defend the wires against the deleterious action of hot gases. When necessary, protection is afforded these tubes by enclosing them in steel jackets.

Heavier types of thermo-electric pyrometers consist of a *rod* of one metal fitted tightly into one end of a cylinder concentric with the rod and of another metal and insulated from the same by suitable means.

Calibration of thermo-electric pyrometers is effected by immersing the protected couple in substances or the vapour of substances whose melting or boiling points are known. The couple, being subject to like thermal changes as the substance, causes a fluctuation in the current flowing within the closed circuit, which fluctuation is registered by the instrument within the circuit. For example, while solidification of a metal in which the protected couple is immersed is in progress a constant reading is obtained on the instrument. This value is observed, and is recorded on a graph against the melting point of the metal as ordinate. A series of such points may be obtained by employing a number of metals in similar manner to that already described, and, these points being united, a curve is obtained from which the temperature corresponding to any given reading of the instrument may be abstracted.

The following are the melting points on the thermo-dynamic scale used by the Washington Bureau of Standards as standard temperatures in the standardisation of thermometers and pyrometers :—

Mercury	— 38·9° C.	Antimony	630·0° C.	Nickel	1452° C.
Tin	231·9 „	Aluminium	658·7 „	Iron	1520 „
Cadmium	320·9 „	Silver	960·5 „	Palladium	1549 „
Lead	327·4 „	Gold	1063·0 „	Platinum	1755 „
Zinc	419·4 „	Copper	1083·0 „	Tungsten	3000 „

At temperatures of 1000° C. the error is of the order of 0·1° C., at the melting point of platinum 5° C., at that of tungsten 100° C. A further table of other standard temperatures is given in which the following are included :—Normal boiling-point of oxygen 180·0°, sublimation of carbon dioxide in an inert liquid 78·5°, normal boiling point of water 100°, of naphthalene 217·96°, of benzophenone 305·9°, of sulphur 444·6°, freezing point of sodium chloride 801° C.

In the *Physical Review* the melting point of rhodium is estimated to be at 1907 or 1968° C. and that of iridium as 2292 or 2388° C. That of silicon is placed at 1434 or 1452° C. and that of palladium at 1548 or 1576° C. The reason for the two figures is due to the fact that the calculations are based on different estimates of the melting-point of platinum, which has been placed at 1745° C. by some experimenters and at 1789° C. by others.

Electric Resistance Pyrometers.

In these instruments advantage is taken of the change of resistance of a wire with temperature. Platinum wire is generally employed. The essential features of the commercial apparatus are a coil of fine platinum wire, enclosed in a suitably designed protecting tube, a cell or accumulator for the supply of current to the wire and an indicator or recorder on which the temperature may be read off directly.

In the original type of this instrument errors due to the residual strain and impurities in the lead wires entered, but later instruments are designed with 'compensating wires,' whose component parts are equal in resistance to and are so arranged that they are heated to the same temperature as corresponding parts of the lead wires. Changes in resistance in the lead wires are compensated by equal changes in the 'compensating wires.'

The resistance pyrometer (after Callendar) is represented diagrammatically in fig. 11.

P represents the pyrometer coil; AM, KN the lead wires; CL, DL the 'compensating wires'; FK a bridge wire with scale, so arranged that 1 cm. length of the same corresponds to 1° C. rise or fall of the temperature, H the sliding contact piece, and G a galvanometer. AB and BC are wires of equal resistance. DE represents a set of resistance coils. In practice AB, BC and DE can be

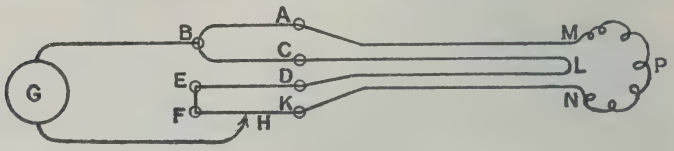

FIG. 11.

replaced by a post office box. Balance is obtained by the adjustment of the resistances in DE and the sliding of the contact piece H. The resistance of the pyrometer coil is given by the sum of the coils DE and the bridge wire scale reading.

Resistance pyrometers are accurate from 0° C. to 1000° C., and are employed industrially wherever reliable measurement is essential. They suffer owing to their high first cost and their fragile character. There are, however, large numbers of this type of pyrometer in use commercially.

METALS AND ALLOYS.

ALLOYS.

There are three well-recognised types of alloys:—

(i) Conglomerates of metals, or of metals and non-metals.
(ii) Homogeneous mixtures of metals, or of metals and non-metals.
(iii) Inter-metallic compounds, or compounds of metals with non-metals.

(i.)

In this type of alloy the component elements or their compounds crystallise out from the molten alloy in a practically pure state, and the addition of one component to the other results —within certain limits—in a lowering of the solidifying point of the resulting alloy. The alloy having the lowest solidifying point in such a series is called the 'eutectic.' Lead-tin alloys are of this type.

(ii.)

In this type of alloy the component metals do not crystallise out from the molten alloy in the pure state, but contain on freezing more or less of each other in solid solution. Copper-nickel alloys are of this type.

(iii.)

Inter-metallic compounds behave similarly to pure metals, crystallising in like manner. Copper and zinc form a compound Cu_2Zn_3, which is extremely hard and brittle.

IRON.

IRON (FERRITE).

Chemically pure iron is not an article of commerce at the present time. Iron has been obtained by electrolytic deposition of a degree of purity greater than 99·9 per cent. iron, while the American Rolling Mills Co. manufacture a commercial product which they claim to contain 99·84 per cent. of iron.

Stead, by extrapolation, has arrived at the following figures for the approximate mechanical properties of pure unworked iron :—

Yield point	9 tons per square inch.	Elongation .	51 per cent. (length/area=8).
Maximum stress	17 ditto.	Reduction in area	84 per cent.

The term ' Ferrite ' is applied to pure iron when it is considered as a microscopical constituent of iron or steel. Pure iron is composed of polyhedral crystallites of ferrite.

Carbon, manganese, silicon, sulphur, phosphorus, arsenic, molybdenum, etc., all have effect on the iron in which they occur and are frequently added with a view to obtain alloys having more or less definite physical and mechanical properties.

INGOT IRON.

' Ingot Iron ' is the generic name of a commercially pure iron produced under patents owned by the International Metal Products Company. The manufacture of the metal in Great Britain is controlled by The Armco International Corporation, which company also undertakes the sale of the metal in various forms throughout the world, through suitable agents and representatives.

Ingot Iron, unlike Puddled Wrought Iron, is produced in the basic open-hearth furnace, and in view of a certain amount of difficulty in finding an acceptable definition of ' iron ' and in differentiating between ' iron ' and ' steel,' it is well to quote the definitions advanced by Dr. Albert Sauveur, who recently received the Bessemer Medal given by the British Iron and Steel Institute Dr. Sauveur says :—

' COMMERCIAL IRON is the element iron as pure as it can be commercially produced.

' INGOT IRON is commercial iron which has been produced in a fluid condition and cast.

' WROUGHT IRON is a ferrous metal which is malleable and which has been produced from a pasty condition.

' STEEL is an alloy of iron and carbon which is malleable, usually containing substantial quantities of manganese.'

'ARMCO ' INGOT IRON is ingot iron produced in the open-hearth furnace containing less than 0·02 per cent. carbon and less than 0·035 per cent manganese.

' Armco' Ingot Iron possesses many special characteristics, some or all of which will appeal to fabricators and users in many industries. The principal points of merit are as follows :—

Chemical Purity.—' Armco ' Ingot Iron contains less than one-sixth of 1 per cent. of impurities considering silicon, sulphur, phosphorus, manganese, carbon, copper, and the gases oxygen, hydrogen, and nitrogen.

Uniformity.—The method of manufacture of Ingot Iron and its freedom from impurities ensure uniformity of analysis ; this, coupled with the fact that the metal is free from slag inclusions, such as exist in even the best puddled irons to a greater or lesser degree, ensures mechanical uniformity.

Corrosion Resistance.—The conclusion that pure iron resists rust is not merely derived from theoretical inference, but represents the definite finding of many observers of the problems of corrosion, after fully investigating generations of service evidence in the form of old hand-wrought irons, such as, for example, the Iron Pillar of Delhi. These old irons were not rustless, but they resisted rust and corrosion to a remarkable degree, by reason of their freedom from corrosion-promoting impurities.

Workability.—Ingot Iron being a dense, ductile, and uniform metal, possesses exceptional working qualities.

Welding Properties.—The superior welding qualities of Ingot Iron are due to its purity and homogeneity. Being of perfectly even texture and density throughout, it welds evenly and easily.

Paint-Holding Surface.—It has been found in service that Ingot Iron sheets require painting less often than other iron and steel sheets. This is partly explained by its velvety surface, which grips and holds paint tightly, and partly by the degasification which the metal undergoes during manufacture, thereby reducing to a minimum occluded gases which in course of time tend to become liberated, and cause flaking of the paint film.

Enamelling Properties.—' Armco ' Ingot Iron constitutes (it is claimed) the best base known for vitreous enamelling, for the following reasons :—

It is chemically and mechanically uniform.
Its velvety surface grips and holds the vitreous coating.
Its degasification during manufacture reduces the risk of pinholes, blisters, and other blemishes to a minimum.
It shows less tendency to warp than other ferrous metals during the vitreous process.

Electrical Properties.—'Armco' Ingot Iron possesses a high magnetic permeability and low retentivity. It is further a better conductor of electricity than steel; in this connection the following is the result of tests undertaken by the National Physical Laboratory :—

Resistivity

By relative mass = 5·43. By relative volume = 6·17.
(Compared with the British standards for soft copper.)

This superiority in electrical conductivity renders the metal specially suitable for telegraph wire, bond wires, conductor rails, etc.

INGOT IRON can be supplied by *The Armco International Corporation* in the form of black and galvanised sheets, plates, billets, bars, shapes, wire, rods, welding rods, cold rolled strip, and welded tubes.

WROUGHT IRON.

Wrought iron is iron low in carbon content, which in course of production is in a pasty condition, owing to the fact of its being worked at a temperature too low to render it fluid. It contains a relatively large percentage of non-metallic impurities in the form of slag, which may be readily seen when the iron is examined microscopically, and which, therefore, serves, among other features, to distinguish this product from steel. The percentage of carbon in wrought iron rarely exceeds 0·15 per cent., and the total of other elements present in the metal is generally less than 0·25 per cent. Wrought iron is not appreciably hardened by quenching.

The fracture of wrought iron is fibrous in appearance and is occasionally characterised by the presence of somewhat large proportions of non-metallic inclusions.

WROUGHT-IRON (*or Mitis*) CASTINGS.

If a small amount of aluminium is added to a charge of wrought iron which has been heated until pasty, the iron immediately liquefies, and can be poured into castings having all the properties of wrought iron except fibre, and as sound as if of cast iron. These castings are called 'Mitis' castings because of their softness in contrast with cast-iron castings.

The best results are obtained by using Swedish scrap iron or English hematite iron, that is, materials containing less than 0·1 per cent. of phosphorus, which is a very injurious ingredient if present in much larger quantity. Using a mixture with poorer quality of iron, with phosphorus running up to 0·15 per cent., good results may still be obtained—that is, the castings still compare favourably with ordinary malleable castings. The following mixture for melting has been used :—Mitis scrap, 35 per cent.; hematite muck bar, 35; wrought-iron punchings, 12¾; soft steel scrap (0·1 per cent. carbon), 12¾, white pig iron, 3; ferro-silicon (10 per cent. silicon), 1; ferro-aluminium (6 per cent. aluminium), ¾.

In general it may be said that if iron free from impurities is used very good castings are obtained; if iron is used with a large percentage of phosphorus, proportionately brittle and unsatisfactory castings result.

The ferro-aluminium used should be, for similar reasons, free from any considerable amount of such impurities as generally injure wrought iron.

PIG IRON.

Typical Analyses of Pig Iron, etc.

The following list of analyses is taken from Dr. W. H. Hatfield's book, 'Cast Iron in the Light of Modern Research.' It is published with the kind permission of the author and of the publishers, C. Griffin & Co. Ltd.

CAST IRON.

Foundry Practice.

1.

The physical and mechanical properties of the products of the cast-iron foundry are almost entirely dependent on the condition of the carbon in these products. The carbon in cast iron can occur either in a free state, as graphite, or in combination with iron, as a carbide of iron, Fe_3C, or with iron and manganese, as a double carbide $(Fe, Mn)_3C$. Foundry practice consists almost entirely of the control of the degree of graphitisation of the carbides present in the cast iron produced.

The graphitisation of these carbides tends to increase—

(*a*) With the temperature.
(*b*) With deceleration of cooling.
(*c*) With the content of silicon, nickel, or aluminium.
(*d*) With the number of graphite nuclei in the iron.
(*e*) With the total content of carbon

Graphitisation is prohibited—

(*a*) By the presence of sulphur, oxygen, vanadium, or chromium.
(*b*) By the presence of manganese under certain conditions.
(*c*) By acceleration of cooling.

It will be seen that by the variation of the above factors an immense number of conditions can be obtained. It is in the scientific control of these that much of the success in foundry practice lies.

2. The Influence of Carbon on Cast Iron.

The strength, hardness, density of structure, etc., of cast iron are dependent almost entirely on the relative quantities of carbide and graphite in the same.

An increase in the ratio $\frac{\text{Carbide}}{\text{Graphite}}$ leads to—

(a) An increase in hardness, brittleness, and density of structure.
(b) A decrease in machinability and ductility.

The strength of cast iron reaches a maximum when the combined carbon content is between 0·80 per cent. and 1·00 per cent.; if the combined carbon content given above is exceeded a reduction in strength, which only terminates when the carbon is entirely in the form of carbide, is witnessed. The following figures, given by Howe, are of value in this connection :—

As the tensile strength increases	From less than 20,000 lbs. per sq. in.	To more than 35,000 lbs. per sq. in.	Or by more than 15,000 lbs. per sq. in.
The total carbon content decreases .	from 3·69 per cent.	to 2·98 per cent.	or by 0·71 per cent.
The graphite content decreases . .	from 3·12 „	to 2·22 „	or by 0·90 „
The combined carbon content increases	from 0·57 „	to 0·76 „	or by 0·19 „

The above table classifies the results of an examination of 180 samples of cast iron taken without selection.

According to Dr. Stead (British Foundrymen's Association Proceedings, 1915), an increase of each 0·1 per cent. of graphite may reduce transverse strength by 2 cwts. and tensile strength by 0·8 ton per square inch.

The fusibility of the iron carbon alloys increases as the total carbon content increases up to about 4·30 per cent.; beyond this point the melting points of the alloys are raised by additions of carbon. Other effects of increased total carbon are decreased tensile strength, increased machinability and decreased chilling power. The last phenomenon is occasioned by the difficulty of retaining carbon as carbide, which naturally increases as the amount of carbon to be thus retained increases. Given suitable means for preventing graphitisation, every increase in the content of total carbon leads to an increase in the hardness of the chilled surface of the alloy in question.

The machining of cast iron containing more than 0·80 per Cent. of combined carbon is practically impossible.

3. The Influence of Silicon on Cast Iron.

Silicon varies from 0·20 to 4·00 per cent. in cast iron, but rarely exceeds 3·50 per cent. or falls below 0·50 per cent. It is present in cast iron, in all probability, as silicide of iron (FeSi), which is dissolved in the pure iron, or ferrite, of the alloy. The presence of this compound tends to strengthen and harden the ferrite. Silicon, however, has the effect of rendering cementite unstable, with the result that there is a tendency towards the formation of ferrite and graphite. Starting with white cast iron, the addition of silicon up to 1·00 per cent. results in an almost proportional decrease in the chilling power of the iron. Again, the addition of silicon to white cast iron leads to an increase in the strength of the resulting irons; this factor reaches a maximum when the content of combined carbon in the alloy is between 0·80 per cent. and 1·00 per cent. As the silicon percentage is further raised so are the combined carbon content and the strength of the cast iron lowered. When the silicon content is above 2·00 per cent. its hardening effect on ferrite is noticeable, iron relatively hard to machine being occasionally improved by a reduction of the silicon content.

The presence of silicon leads to a depression of the melting-point of cast iron; in similar manner the percentage of carbon in the eutectic alloy is reduced from 4·30 per cent. to 3·40 per cent. as the percentage of silicon increases up to 3·00.

Silicon has the effect of reducing the shrinkage of cast iron.

As a means of determining the correct proportions of carbon and silicon in cast iron, the following formula has, according to Mr. F. J. Cook, been used with marked success in practical working :—

$$X = \frac{C}{4{\cdot}26 \times \frac{Si}{3{\cdot}6}},$$

where C = *total* carbon in percentage;
Si = silicon in percentage.

The elements carbon and silicon are in the best proportion when the value of X is as given below :—

For Ordinary work such as pans, grates, easily machined casting and pipes	X = 0·9 to 1
Locomotive cylinder (maximum transverse strength)	„ = 0·83
Steam, gas, Diesel and hydraulic cylinders (maximum tensile strength)	„ = 0·76 to 0·82
Chilled castings	„ = 0·75 to 0·8
Acid resisting	„ = 0·85

4. The Influence of Sulphur on Cast Iron.

Sulphur combines with iron to form a sulphide having a low melting point, which occurs in steel in the form of ovoids, oval laminæ or membranes enveloping the ferrite grains. The presence of this sulphide is the cause of red shortness.

In cast iron this sulphide may modify the properties of the alloy owing to its manner of aggregation, but it is deleterious chiefly on account of its tendency to segregate and its powerful effect on shrinkage, which it increases. Sulphur tends to restrain graphitisation, hence it increases the chilling power of cast iron and may, therefore, be termed a hardening agent. This element should, however, be employed with great caution, if at all, in this capacity, on account of the objectionable properties previously stated. The presence of sulphur makes the molten metal thick and sluggish, giving rise to blowholes, yet this element in fair proportions, say 0·12 per cent., adds considerably to the wearing properties and strength of the metal. In every case, however, sulphurous iron *must* be cast as hot as possible if trouble is to be avoided.

Manganese and silicon are employed to counteract the evil effects of sulphur. Manganese reacts with iron sulphide, with resulting formation of manganese sulphide and liberation of iron. Under certain circumstances manganese sulphide is removable from cast iron, but even when retained its effects are not so deleterious as are those of iron sulphide. Silicon, owing to its strong tendency to induce graphitisation, resists the effect of sulphur in tending to retain carbon in the combined condition; it does not remove sulphur, nor does it prohibit the shrinkage due to sulphur or reduce the tendency towards cracking.

Sulphur is frequently limited by specification to 0·05 per cent., but in the hands of experienced and careful workers as much as 0·20 per cent. can be allowed without ensuing unsoundness. If the sulphur content of an iron is to be low the conditions under which it is prepared must be such that sulphur tends to be eliminated. Hence, coke low in sulphur must be used and suitable fluxes should be employed in the furnace for removing sulphur from the metal, *e.g.* lime, fluor spar or manganous oxide.

5. The Influence of Manganese on Cast Iron.

Manganese and iron unite to form a series of solid solutions whose freezing-point curve lies entirely between the freezing points of the component metals. The freezing points of all the alloys of pure iron and pure manganese are below that of pure iron. The freezing point of cast iron is depressed by the addition of manganese, not only on the above account but also owing to an increase in the degree of solubility of carbon in cast iron, which is brought about by the fact that the affinity of manganese for carbon is greater than that of iron for carbon. The depression of the freezing point reaches a maximum when the percentage of manganese is about 13.

The alloys of iron and manganese (pure) are harder than pure iron. Manganese therefore would, normally, have the effect of hardening the ferrite of cast iron were it not for the fact that its affinity, firstly for sulphur, and secondly for carbon, prohibits its solution in the ferrite.

Manganese, when added to cast iron, combines in the first place with such sulphur as is present in the iron; any excess above that required for the formation of manganese sulphide unites with iron carbide, with the formation of a double carbide of iron and manganese.

The quantity of manganese required to effect the entire conversion of the iron sulphide in the alloy into manganese sulphide is considerably more than that indicated by the equation—

$$FeS + Mn = MnS + Fe.$$

Manganese sulphide is characterised by the following physical properties:—

(1) High melting point—1400° C.;
(2) Insolubility in molten iron;
(3) Low specific gravity;

all of which assist in bringing about the separation of both manganese and sulphur from the molten alloy. Rapid cooling of the molten alloy leads to the more or less complete retention of manganese sulphide in the resulting solid alloy; slow cooling assists in separating the sulphide and bringing it into contact with the slag found on the surface of the alloy when the same is, for example, in the ladle. When the metal does not remain long enough in the ladle, or is not hot enough for the above to take place quickly, the manganese sulphide will be found on the top part of the casting in the form of hard spots, which are difficult to tool. Iron sulphide is deleterious in its action upon iron and steel. Manganese sulphide, though not beneficial, is of a somewhat neutral character. Manganese is, therefore, valuable as a desulphuriser.

Such manganese as is present in cast iron in excess of that required for the transformation of iron sulphide into manganese sulphide combines with the carbide of iron to form a double carbide, as stated above. Manganese is generally considered to induce the retention of the carbon in combination. This is true, but this effect does not make itself felt until the manganese content is well above that usually found in foundry irons. Hence, though hardness is increased by the addition of manganese, the cause is not usually the retention of carbon as carbide.

On the whole it may be said that, owing to (1) the tendency of manganese to produce brittleness and coarse crystallisation, and (2) its activity as a deoxidiser, it is inadvisable to add manganese to cast iron for the sole purpose of increasing hardness and chilling power.

Manganese increases the shrinkage of cast iron.

6. The Influence of Phosphorus on Cast Iron.

Phosphorus combines with iron to form a number of compounds, of which one, that containing three molecules of iron to each molecule of phosphorus, is of common occurrence in cast iron. The presence of phosphorus effects a reduction in the melting-point of cast iron and a reduction in the total carbon content of cast iron.

As the phosphorus content of cast iron is increased up to about 0·40 per cent. so is the strength of the cast iron increased. Further additions of phosphorus appear to have but slight effect on the strength of cast iron until the percentage reaches about 0·75 per cent. Above this point the alloys are liable to be brittle, and unless fluidity is more important than strength 0·75 per cent. of phosphorus should not be exceeded. For thin castings in general, which are not required to be strong, the phosphorus can be increased to 1·5 per cent. or more, but in thin castings such as automobile cylinders, which are required to withstand wear and tear, not more than 0·30 per cent. of phosphorus should be allowed, owing to the slight tendency towards segregation of high phosphide irons.

7. The Influence of Nickel on Cast Iron.

The effect of the addition of nickel to grey iron (carbon 3·6, silicon 1·4) is shown in the following table:—

Nickel. %	Transverse Strength. Tons per sq. in.	Tensile Strength. Tons per sq. in.
0	1·52	10·0
0·5	1·78	13·7
1·0	1·96	14·5
1·5	1·99	14·6
2·0	1·98	14·5

The increase in transverse, tensile, and compressive strength of grey iron due to the addition of from 0·5 to 5 per cent. nickel varies from 10 to 50 per cent., depending on the composition of the iron and other factors. The presence of 0·5 per cent., and preferably up to 0·8 per cent., combined carbon is essential. If by reason of high silicon or total carbon the combined carbon is below the limit given, it should be raised, either by adding chromium with the nickel in the proper ratio, or by reduction of the silicon or total carbon, allowing the nickel to replace silicon in eliminating the excess combined carbon, if any.

The effect of the addition of nickel to a cast-iron mixture is to—(*a*) refine the grain; (*b*) reduce and control chill; (*c*) reduce porosity; (*d*) increase the strength and hardness and simultaneously improve the machinability; (*e*) produce almost uniform hardness from castings of irregular section.

If the iron is partially graphitised in the first place by a small silicon content, then, in general, the graphite present is fine. If, however, the initial silicon content is high enough to give coarse graphite, then the addition of nickel renders the graphite flakes finer; with very high silicon (3 per cent.) the effect is less marked.

Silicon itself exerts a similar effect to nickel on graphitisation, and in a more marked degree. In this respect one part of silicon may be said to equal 2–4 parts of nickel, but the use of silicon for reducing the chill entails progressive impairment of physical properties—more open grain, greater tendency to porosity and internal shrinkage, and decreased hardness and strength. While nickel acts powerfully to reduce the combined carbon to the free carbide point—about 0·9 per cent.—it only acts mildly beyond that point, and does not tend to open the grain and soften the iron when present in excess.

Machinability alone can be improved also, and more cheaply, by the use of higher silicon, but with attendant impairment of the physical properties. Silicon secures machinability by graphitisation alone, and this lowers the hardness. The addition of nickel produces a progressive and uniform hardening of the iron matrix (producing sorbite) instead of through an increase of carbides. As nickel both hardens iron and reduces chill simultaneously it is possible, by the use of 1–3 per cent. nickel, in a casting of varying section to harden the heavy section and at the same time render the light section more machinable. In comparatively heavy sections with high silicon irons up to about 0·6 per cent. chromium may be used.

Reduce machining costs!

WITH Ley's 'Black Heart' Malleable, machining troubles disappear because firstly, there are no hard spots in Ley's malleable, and secondly there is a natural lubricating effect from the temper carbon (which makes the metal as free-cutting as many of the special free-cutting steel bars).

Consult us on malleable machining problems; we can probably tell you at once from our experience exactly what savings you could effect by changing over to Ley's Malleable.

8. The Influence of Chromium on Cast Iron.

The influence of chromium is (*a*) increase in the total carbon content; (*b*) increase in the combined carbon; (*c*) increase in the hardness; (*d*) increase in the transverse strength up to 1 per cent. chromium. The proper use of a small percentage of chromium will enable the amount of combined carbon to be raised and adjusted. In addition, certain combinations of nickel and chromium (*e.g.* 1 per cent. Cr, 3 per cent. Ni) have a greater hardening and strengthening effect than either element alone. The hardening properties of chromium are especially valuable for castings subjected to abrasion. Excessive amounts of chromium produce hard spots of chromium carbide which renders castings unmachinable—therefore, in light sections, it is advisable to use nickel alone. In general, the chromium should not exceed 0·5 per cent., nor the ratio 1 part to 3 parts of nickel.

(*Bureau of Information on Nickel.*)

9. Semi-Steel.

Semi-steel is simply cast iron made from a furnace charge of cast iron to which **mild steel or wrought iron** has been added. Additions **of from 10 to 25 per cent. of steel** are usual, **but 30 and occasionally 40 per cent. are not unknown. As steel is low in carbon, silicon and phosphorus, the final cast iron (for it is still a true cast iron) is low in these elements. The steel should be added as sheared clippings or other small pieces, but not as borings, which take up too much sulphur. Iron appears not to take up sulphur from gases, but only by direct contact with the coke, hence the air furnace gives irons lower in sulphur than the cupola and is specially suited for melting steel with pig irons. Perfectly good results are,** with care, **obtainable from the cupola.** There is, however, a tendency for the more fluid portions of a cupola burden of cast iron and steel to run first. Hence the first tap from the cupola is generally higher in carbon content than succeeding taps.

Tests for Cast Iron.

(Abstract of paper read by Mr. F. J. Cook before the Staffordshire Iron and Steel Institute, January 20, 1917.)

Important tests which are of use as a guide to foundrymen are :—

(1) Keep's shrinkage test;
(2) Transverse test;
(3) Hardness test;
(4) Casting temperature or fluidity test;
(5) Impact test.

(1) **Keep's Test** consists of casting ½ in. square bars between iron yokes, the ends of which are 12 ins. apart. When the bars have cooled down the shrinkage is shown by the difference between the length of the bars and the gap in the yoke in which they were cast; this is usually measured by inserting a taper graduated wedge in the gap and measuring off the dimension of the space.

This test is quite a comparative one, and when the amount of shrinkage which is associated with the most satisfactory castings has been arrived at, any deviation can be rectified by a little addition of silicon if the shrinkage becomes too high and *vice versa* when it is too low.

Under normal conditions a shrinkage of 0·183 in. = 1 per cent. silicon, and, to take the other extreme, 3·5 per cent. silicon is associated with 0·123 in. shrinkage.

(2) **Transverse Test.**—The following table gives average particulars of shrinkage, deflection and breaking load obtained with various classes of iron :—

Class of Material.	Shrinkage.	Deflection.	Breaking load.
	in.	in.	lbs.
Tough strong Iron	0·160	0·25	550
Hard „ „	0·168	0·22	630
Soft Iron	0·123	0·18	423
Mottled Iron	0·207	0·11	375
White Iron	0·226	0·08	250

from which it will be seen that to obtain a big deflection strong irons are necessary.

(3) **Hardness.**—The most handy and reliable form of test is the 'drill test,' as all other methods deal with surface hardness only. The test may be made as follows :—Cast the metal into bars 1½ in. diameter, ¼ in. being shaped off one side to give a flat surface to work upon, and move the outside skin. Drill four holes ⅜ in. diameter, to a depth of 1 in., then the number of revolutions required to drill to this depth (the mean of the four holes being taken) indicates the

general hardness. The angle of the drill should be ground exactly the same for each test, by means of a suitable guide on the grinding machine. It is also essential to keep the same drill for the purpose, and preferably, two drills should be used and two holes drilled with each, which minimises many discrepancies which otherwise might come in. The efficiency of drills is materially affected by the sharpness of their point, and as cast iron is often not homogeneous and may contain more or less hard spots a false result may be obtained owing to the point becoming unduly dulled by striking a hard spot in the early stages of the test. To avoid this a hole $\frac{1}{8}$ in. diameter should be first drilled, which affords clearance for the point of the drill and ensures the full cutting edge coming into operation. It is obviously necessary that the same weight be attached to the drill and also that it runs at the same number of revolutions per minute for each test.

(4) **Casting Temperature.**—Low silicon cast iron is very prone to the effects of casting temperature, and some irons employed for such purpose are also liable to liquid contraction. A handy workshop test for casting temperature with this class of iron consists in making bars of the general dimensions shown in fig. 12. When cold the bars are broken through the line AB, the condition of the fracture giving an indication of the temperature at which

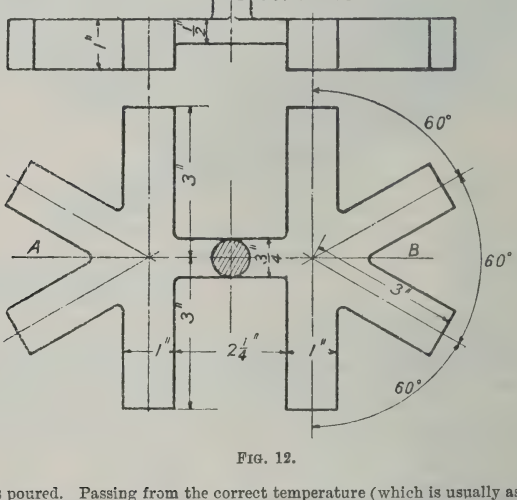

FIG. 12.

the metal was poured. Passing from the correct temperature (which is usually as hot as can be obtained from the cupola) to very low, the following fractures will be observed—perfectly solid and homogeneous, then slight whitish centre, then brown centres of varying sizes and depth of colour as temperature is lowered and then black centre; with the latter is always associated open cavities, and immediately above them is invariably found a gas hole.

For softer cast iron, which can be cast at a lower temperature without suffering the same effects as low silicon irons, a test bar in the form of a wedge is a very useful guide as to the fluidity of the metal. Dimensions of such a test-bar used by the British Chuck and Piston Ring Co. are length 9 ins., width 1 in., $\frac{3}{8}$ in. thick at the largest end tapering to $\frac{1}{32}$ at the smaller, the bars being run from the thick end.

(5) **Impact Test.**—A satisfactory test is on bars 40 mm. square (1·57 in.) supported on knife edges 160 mm. (6·3 ins.) apart, and by dropping a weight of 12 kilos (26·5 lbs.) from a height of 30 cm. (11·8 ins.) increasing the height of drop by increments of 5 cm. (1·9 in.) until such times as the sample breaks, the height at which the bar eventually fractures being taken as the impact figure. Attached to the weight, in such a manner as to strike the bar parallel to the supporting knife edges, and the centre of same, is another knife edge. The face of all the knife edges should be rounded $\frac{1}{16}$ in. radius.

A result of 55 cm. (21·5 ins.) is none too high for the work named, although this is quite a severe test. The maximum attained, as far as is known, has been 80 cm. (31·3 in.).

STEEL.

(Contributed by Ernest W. Birch, A.M.I.A.E.)

The term 'steel' is applied in a general sense to those alloys of iron and carbon whose carbon is present entirely, or almost entirely, in the combined condition and whose total carbon content does not exceed 2·00 per cent. In a special sense the term is applied to alloys of iron and carbon with elements which are generally in excess of the carbon and whose presence considerably modifies the resulting alloys; such alloys are generally referred to as 'alloy or special steels.'

Steel is always contaminated by some or all of the elements—manganese, silicon, sulphur and phosphorus, and the allowable percentages are given in the following specifications. Sulphur and phosphorus should be kept as low as possible owing to the detrimental effect of these elements.

Carbon renders the steel susceptible to hardening, although below 0·2 per cent. steel shows no appreciable hardening effect when rapidly cooled. As the carbon percentage increases, so does the tenacity and hardness, with a corresponding reduction in the ductility and toughness.

Steel is generally graded according to the percentage of carbon present. A general classification is as follows:

Carbon under 0·10 per cent.	Dead soft steel, very mild or extra mild steel, very low-carbon steel.
Carbon 0·10 to 0·25 per cent.	Mild steel, soft steel, low-carbon steel.
Carbon 0·25 to 0·60 per cent.	Medium-carbon steel, medium high-carbon steel, half-hard steel.
Carbon 0·60 to 1·20 per cent.	High-carbon steel, tool steel, hard steel.
Carbon over 1·20 per cent.	Extra-hard steel, very high-carbon steel.

The classification is not rigid, as no attempt has been made to standardise the various grades. A further classification is made with carbon tool steels, the steels being graded according to their 'temper.' (This term has no connection with the term 'tempering,' used in thermal treatment.) The Temper numbers are arbitrarily chosen by the makers, and the following is an example:

Temper No.	Carbon Content.
	Per cent.
1	1½
2	1¼
3	1⅛
4	1
5	⅞
6	¾

The critical points in a straight carbon steel are dependent on the amount of carbon present, and these critical points control the temperature for forging, annealing, hardening, and tempering. The higher the carbon content the lower the critical temperatures and the more sensitive is the steel. For the before-mentioned steels the recommended working temperatures are as follows:

Carbon Content. Per cent.	Forging Temp. ° C.	Annealing Temp. ° C.	Hardening Temp. ° C.
1½	800	720	760
1¼	825	720	760
1⅛	850	720	770
1	875	720	770
⅞	900	750	785
¾	950	770	800

The tempering temperature depends on requirements. The higher the reheating (tempering) temperature, the greater is the loss in hardness, with a corresponding increase in the ductility (see pp. 1063 and 1070).

Carbon Content.	Suitable for:
Per cent.	
1½	Special turning and planing tools.
1¼	The most suitable for turning and planing tools, twist drills and small cutters.
1⅛	For large turning tools, circular cutters, taps, small punches, reamers, screwing dies, and small shear blades.
1	For hot setts, large punches, large taps, cold chisels, etc.
⅞	For chisels, setts, dies, smiths' tools, large shear blades, masons' tools, etc.
¾	For hammers, general dies, and miners' drills.

Having selected the correct quality steel for the particular purpose, it is essential to give the correct heat treatment in order to obtain the best results. The hardening temperatures are given in the previous table. The following table gives the necessary tempering temperature:

Tempering Temperature, ° C.	Suitable for:
300	Springs.
298	Wood saws.
295	Circular saws for metal.
290	Cold chisels for wrought iron.
285	Moulding and planing cutters for soft wood, needles, cold chisels for cast iron.
280	Firmer chisels, saws for bone and ivory, cold chisels and setts for steel, gimlets.
275	Hot setts, axes, and adzes.
270	Augers, pressing cutters, flat drills for brass.
265	Coopers' tools, wood borers, twist drills, stone-cutting tools.
260	Plane irons, gouges, planing and moulding cutters.
255	Moulding and planing cutters for hard wood, punches and dies, cups, snaps, and shear blades.
250	Penknives, chasers, mill chisels and picks, taps, rock drills, screw-cutting dies.
245	Leather-cutting dies, boring cutters, reamers.
240	Bone-cutting tools, milling cutters, drills, wood engraving tools.
235	Paper cutters, planers for iron.
230	Ivory-cutting tools, planes for steel, screwing dies for brass, hammer faces.
225	Light turning tools, steel engraving tools.
220	Scrapers and lathe tools for brass.

HIGH-SPEED TOOL STEELS.

Type.	Commonly called—
A. Low Tungsten (13 per cent.)	'Twist Drill' quality
B. Medium Tungsten (15 ,,)	'Standard' quality
C. High Tungsten (18 ,,)	'Super' quality

CARBON AND ALLOY STEEL SPECIFICATIONS.

The following data are based upon B.E.S.A. Report 5005–1924 and upon the very complete specifications prepared by the S.A.E. (Society of Automotive Engineers, U.S.A.).

The range of steels given covers practically all general requirements. The selection of a given steel for a given part must depend upon an intimate knowledge of a number of important factors, such as the detailed design of the part and the severity of the service to be imposed, whether the part is to be machined or forged, machinability, and the method of manufacture. From the data given, a steel can be selected from a consideration of physical properties, after which the final choice depends upon such considerations as machinability, heat-treatment, etc.

CARBON STEELS.

Reference No.	Carbon Range.	Manganese Range.	Phosphorus. Max.	Sulphur. Max.
1	0·05–0·15	0·30–0·60	0·045	0·05
2	0·10–0·20	0·30–0·60	0·045	0·05
3	0·15–0·25	0·30–0·60	0·045	0·05
4	0·20–0·30	0·50–0·80	0·045	0·05
5	0·25–0·35	0·50–0·80	0·045	0·05
6	0·30–0·40	0·50–0·80	0·045	0·05

8	0·40–0·50	0·50–0·80	0·045	0·05
9	0·45–0·55	0·50–0·80	0·045	0·05
10	0·90–1·05	0·25–0·50	0·045	0·05
11	0·45–0·55	0·90–1·20	0·045	0·05
12	0·55–0·70	0·90–1·20	0·045	0·05
13	0·08–0·16	0·60–0·80	0·09–0·13	0·075–0·15
14	0·15–0·25	0·60–0·90	0·06– max.	0·075–0·15

Steels Nos. 1 and 2.—Used for tubing and pressings; they are soft and ductile and will stand much deformation without cracking. Low tensile strength in annealed condition, but the yield point can be raised considerably by cold-working. They do not machine freely and will tear badly in turning, threading, or broaching. Machining properties can be improved by quenching in water from 925° C. Suitable for case-hardening.

Steel No. 3.—Forges well and machines better than No. 1 and 2. Can be used for machined forged, and case-hardened parts where no great strength is required. Can be drawn into tubes and cold rolled, and for cold-worked shapes that do not require deep drawing. When cold worked, yield point 18–35 tons per sq. in. in rounds not over $\frac{1}{2}$ in. diam. or in flats $\frac{1}{4}$ in. thick. Heat treatment will refine the grain after rolling or forging. Particularly suitable for case-hardening.

Steels Nos. 4 and 5.—Suitable for forged, machined, or cold-worked parts requiring higher physical properties than No. 2, also more responsive to heat-treatment and machines better. These steels should not be used for case-hardened parts.

Steels Nos. 6 and 7.—Medium carbon steels possessing good machining properties, and are suitable for small and medium-size forgings. After heat-treatment Brinell range 174–212.

Steels Nos. 8 and 9.—Medium carbon steels suitable for large forgings. Can also be used for a wide range of parts from bar stock. After heat-treatment Brinell range 192–235.

Steel No. 10.—Suitable for leaf springs and certain coiled springs. Heat-treatment: heat to 760–780° C., quench in oil, water, or brine, depending on size and shape of part. Draw to required hardness.

Steels Nos. 11 and 12.—Suitable for helical springs made of round cold drawn wire up to $\frac{3}{16}$ in. diam. No. 11 steel is recommended for wire from 0·025 to 0·100 in. diam., and steel No. 12 for wire 0·100 in. diam. and larger.

Steels Nos. 13 and 14.—Suitable for 'screw stock'; they machine very sweetly and take a good finish, but owing to cold-shortness they are not suitable for parts subject to shock.

STRAIGHT NICKEL STEELS.

Reference No.	Carbon Range.	Manganese Range.	Nickel Range.
15	0·10–0·20	0·30–0·60	0·40–0·60
16	0·10–0·20	0·30–0·60	1·25–1·75
17	0·10–0·20	0·30–0·60	3·25–3·75
18	0·15–0·25	0·50–0·80	3·25–3·75
19	0·25–0·35	0·50–0·80	3·00–3·50
20	0·30–0·40	0·50–0·80	3·00–3·50
21	0·35–0·45	0·50–0·80	3·00–3·50
22	0·40–0·50	0·50–0·80	3·00–3·50
23	0·45–0·55	0·50–0·80	3·00–3·50
24	0·17 max.	0·30–0·60	4·75–5·25

In all cases sulphur max.: 0·045; phosphorus max., 0·040; silicon, 0·15–0·40.

Steels Nos. 15, 16, and 17 are suitable for case-hardening.

Steel No. 18 not recommended for case-hardening except for massive parts, owing to the reduced ductility of the core due to the increased carbon content.

Steels Nos. 19 and 20 are suitable for parts requiring considerable strength and toughness. Not suitable for case-hardening.

Steels Nos. 21 and 22. As the carbon content is higher than for steels Nos. 19 and 20, higher tensile strength and greater hardness can be obtained after treatment, but with a loss in ductile properties.

Steel No. 23 is suitable for large gears, etc.

Steel No. 24 is used for case-hardened parts that require an exceptionally tough core. When it is necessary to machine parts made of this steel after carburising, the nickel content should be kept as near the lower limit as possible.

NICKEL CHROME STEELS.

Reference No.	Carbon Range.	Manganese Range.	Nickel Range.	Chromium Range.
25	0·10–0·20	0·30–0·60	1·00–1·50	0·45–0·75
26	0·20–0·30	0·50–0·80	1·00–1·50	0·45–0·75
27	0·35–0·45	0·30–0·60	1·50–2·00	0·90–1·25
28	0·17 max.	0·30–0·60	3·00–3·50	1·00–1·50
29	0·20–0·30	0·30–0·60	2·75–3·50	0·50–1·00
30	0·35–0·45	0·30–0·60	3·25–3·75	1·25–1·75
31	0·10–0·20	0·30–0·60	2·75–3·25	0·60–0·95
32	0·45–0·55	0·30–0·60	2·75–3·25	0·60–0·95

In all cases sulphur max.= 0·04; phosphorus max. = 0·04; silicon = 0·15–0·40.

In general these steels give higher tensile values and greater toughness than the corresponding straight nickel steels. They are, however, more sensitive to heat treatment.

Steel No. 25 is primarily intended for case-hardening, but can also be used for structural parts with suitable heat treatment. Where these steels are used for gears where considerable strength and a high degree of accuracy are called for, the gears should be normalised before carburising.

Steels Nos. 28 and 31 are suitable for case-hardening when a core possessing great strength and toughness is required.

The remaining steels are suitable for such heat-treated parts, either machined or forged, as require exceptionally high physical properties, and must be capable of resisting severe dynamic stresses in service.

MOLYBDENUM STEELS.

Reference No.	Carbon Range.	Manganese Range.	Chromium Range.	Nickel Range.	Molybdenum Range.
33	0·25–0·35	0·40–0·70	0·50–0·80	—	0·15–0·25
34	0·35–0·45	0·40–0·70	0·80–1·10	—	0·15–0·25
35	0·45–0·55	0·40–0·70	0·80–1·10	—	0·15–0·25
36	0·10–0·20	0·30–0·60	—	1·5–2·0	0·20–0·30

In all cases sulphur max. = 0·045; phosphorus max. = 0·040.

In general these steels have similar physical characteristics to the corresponding nickel and nickel-chrome steels. Steel No. 36 is suitable for case-hardening.

CHROMIUM STEELS.

Reference No.	Carbon Range.	Manganese Range	Chromium Range.	Sulphur Max.	Phosphorus Max.
37	0·15–0·25	0·30–0·60	0·60–0·90	0·045	0·04
38	0·35–0·45	0·50–0·80	0·80–1·10	0·045	0·04
39	0·45–0·55	0·50–0·80	0·80–1·10	0·045	0·04
40	0·95–1·10	0·20–0·50	1·20–1·50	0·030	0·03

Steel No. 37. This steel is primarily for case-hardening. For structural purposes the chromium content of this steel gives a deeper penetration of the effect of heat treatment than can be obtained in a straight carbon steel having a similar carbon content.

Steel No. 39 is an oil-hardening type of steel intended for heat-treated forgings that require greater strength and toughness than are obtainable with straight carbon steels, or with some of the simple alloy steels having a lower carbon content. It also has a wider heat-treating range than the other simple alloy steels.

Steel No. 40 is used chiefly for the races and balls or rollers of anti-friction bearings. The chromium and carbon contents cause a maximum penetration of the effect of heat treatment and give a high degree of hardness.

CHROME VANADIUM STEELS.

Reference No.	Carbon Range.	Manganese Range.	Chromium Range.	Vanadium.	
				Min.	Desired.
41	0·15–0·25	0·50–0·80	0·80–1·10	0·15	0·18
42	0·25–0·35	0·50–0·80	0·80–1·10	0·15	0·18
43	0·35–0·45	0·50–0·80	0·80–1·10	0·15	0·18
44	0·45–0·55	0·50–0·80	0·80–1·10	0·15	0·18
45	0·90–1·05	0·20–0·45	0·80–1·10	0·15	0·18

Steel No. 41 is intended primarily for case-hardening and can be used for structural parts after suitable heat treatment.

Steels Nos. 42 and 43 These steels can be used in place of the nickel and nickel-chrome steels of similar carbon content for heat-treated forgings requiring greater strength, toughness and resistance to fatigue than it is possible to obtain with straight carbon steels.

Steel No. 45 can be used for anti-friction bearings and is used extensively for machine-tool parts, being primarily a tool steel.

SILICO MANGANESE STEELS.

Reference No.	Carbon Range.	Manganese Range.	Silicon Range.
46	0·45–0·55	0·60–0·90	1·80–2·20
47	0·55–0·65	0·60–0·90	1·80–2·20

Sulphur and phosphorus = 0·045 max.

These steels are essentially spring steels, but may be used for gears. In either case the steel must be suitably heat-treated.

HEAT TREATMENT OF STEELS.

In order to obtain the desired physical properties from steels it is generally necessary to subject them to a thermal treatment. The subject of heat treatment embraces the operations of (*a*) normalising, (*b*) annealing, (*c*) hardening, (*d*) cementing, carburising or case-hardening, (*e*) the tempering or drawing of hardened steels.

The nomenclature and definitions relating to heat treatment as given by B.E.S.A. Report No. 5005–1924 are as follows :

(*a*) Normalising. Normalising means heating a steel (however previously treated) to a temperature exceeding its upper critical range, and allowing it to cool freely in air. It is desirable that the temperature of the steel shall be maintained for about 15 minutes, and shall not exceed the upper limit of the critical range by more than 50° Centrigrade.

(*b*) Annealing. Annealing means reheating followed by slow cooling. Its purposes may be

(1) To remove internal stresses or to induce softness, in which case the maximum temperature may be arbitrarily chosen.

(2 To refine the crystalline structure in addition to the above, in which case the temperature used must exceed the upper critical range as in normalising.

(*c*) Hardening. Hardening means heating a steel to its normalising temperature, and cooling more or less rapidly in a suitable medium, *e.g.* water, oil or air.

(*d*) Cementing. Cementing means heating a steel above its normalising temperature in a medium which will increase its carbon content. The core of a case-hardened bar is the interior portion of the bar which is substantially unaffected by the cementing process.

(*e*) Tempering. Tempering means heating a steel (however previously hardened) to a temperature below its carbon change-point with the object of reducing the hardness or increasing the toughness to a greater or less degree.

(*f*) Refining (cemented parts). Refining means reheating a steel to its normalising temperature, and is usually followed by quenching.

See also p. 2758.

Effect of Tempering.

3½ per cent. nickel steel, oil-hardened at 860° C. and tempered at the temperatures indicated.

Tempered at. ° C.	Yield Point. Tons per sq. in.	Ultimate Stress. Tons per sq. in.	Elongation. %.	Reduction of Area. %.	Impact. Test. Ft.-lbs.	Brinell No.
Not tempered	102·0	116·0	10·0	23·0	6	514
200	92·5	101·0	10·5	32·5	5	461
300	83·0	92·5	12·0	40·0	5	415
400	66·4	76·3	15·1	50·0	11	352
500	54·5	63·5	20·0	59·5	50	285
600	44·0	53·0	25·0	64·5	73	241
650	40·0	49·0	27·0	66·0	82	235

Effect of Mass.

The effect of mass must receive serious consideration when dealing with the physical properties of any heat-treated steel.

The hardening operation consists of heating the steel through and just above its critical range in order to obtain the condition of solid solution, and quenching with sufficient rapidity to retain this condition. With large masses it is practically impossible to obtain a uniform temperature throughout the mass on heating, the interior portion always being at a lower temperature than

the outside. On quenching the heat is absorbed from the outside, and in many cases it is impossible, even with the most drastic quenching, to remove the heat sufficiently rapidly to retain the desired structure in the core. Again, with very thin sections, the rate of cooling may be sufficiently rapid if carried out in air. Only by experience can the effect of mass be correctly estimated.

The following table shows the effect of mass on the physical properties of a 5 per cent. nickel case-hardening steel. Bars of varying diameters were given exactly the same treatment and then tested :

Size of Bar. In.	Heat Treatment.	Yield Point. Tons per sq. in.	Ultimate Stress. Tons per sq. in.	Elongation. %.	Reduction of Area. %.	Impact. Test. Ft.-lbs.	Brinell No.
½	Carburised at 860° C. Reheated to 860° C. Quenched in water Reheated to 750° C. Quenched in water	40·0	51·0	27·0	66·1	55	235
¾		34·5	44·6	31·0	68·3	90	212
1		31·0	40·0	35·0	70·0	105	197
1¼		27·8	37·5	36·7	72·2	111	179
1½		26·7	36·2	36·8	73·5	111	174
1¾		26·5	36·1	37·0	73·5	110	174
2		26·2	36·0	37·0	72·5	104	174
2¼		26·0	36·0	37·0	72·0	90	170

Quenching Liquids.

Liquid quenching mediums include water, brine, oils, and special liquids. Soft water, distilled if possible, is used for hardening ordinary carbon steels. Impurities in the water, such as grease or certain acids, are objectionable, as the former are liable to cause uneven hardness by insulating the steel locally with an oil film, and the acids produce brittleness. Hard water is very unsatisfactory because of the scale thrown down when its temperature is raised. Water to which soap or salt has been added is sometimes used to secure quenching rates respectively lower or higher than that of pure water. Cold sea-water or brine produces extreme rapidity of quenching and consequently maximum hardness. Pieces of complicated design cannot be quenched safely in this medium because of the shock.

Oil-quenching mediums are extensively used where extreme hardness is not required, and where freedom from quenching shock is necessary. These include mineral oils, paraffin, fish oil, whale oil, cotton-seed oil, linseed oil, lard oil, and special animal hydrocarbon oils.

Mineral oils are satisfactory where the quenching bath is kept cool by artificial means. If the oil is not cooled there occurs a gradual breaking down and thickening of the oil with heat, the formation of residue, and wide variation in the quenching rate. Paraffin is dangerous unless kept at a temperature well below its flash point.

Fish and whale oils have the disadvantage of offensive odours and are open to the same objections as the seed oils. Cotton-seed and linseed oils become gummy from oxidation. This increases the viscosity and seriously affects the quenching speed. Lard oil is unsatisfactory because of the tendency to become rancid.

Special oils usually obtained by distillation of wool grease are used extensively with satisfactory results. Artificial cooling of these oils is very necessary when handling large quantities of metal continuously.

Carbonate of lime, mercury, milk, glycerine, soda, tallow, and wax are sometimes used for special cases.

(*Machinery.*)

EFFECT OF NICKEL IN STEEL.

In the annealed condition the average effect of nickel in amounts up to 8 per cent. may be stated as follows:—

Each 1 per cent. of nickel:—

Increases the elastic limit by 1·8 tons per sq. in.
" " tensile strength by 1·9 tons per sq. in.
" " reduction of area by 0·5 per cent.
Decreases the elongation by 1·0 per cent.

For nickel steel with up to 5 per cent. nickel each 1 per cent. of nickel lowers the Ar_1 critical point from 10°–20° C. below those of a corresponding straight carbon steel, and the Ac_3 point from 8°–14° C. The lower the carbon content the greater is the depression of both Ac_3 and Ar_1. With a nickel content of 32–33 per cent. the $Ar_{3\cdot2}$ point is apparently depressed to absolute zero. The addition of nickel also reduces the eutectoid carbon ratio from ·9 per cent. for a straight carbon steel to about ·75 per cent. for a 3½ per cent. nickel steel, and about ·7 per cent. for a 5 per cent. nickel steel.

In the heat-treated condition, the tensile strength, yield point, and hardness are raised with a corresponding reduction in the ductility as compared with a carbon steel. Nickel tends to retard grain growth, thus allowing greater latitude in treating; and a nickel steel may be held above the critical range for longer periods of time without serious injury. On slow cooling, the tendency is to maintain a fine-grained pearlitic or sorbitic structure instead of a full lamellar pearlite.

Nickel further improves the endurance ratio, and this is most marked in the heat-treated condition. Steel with a high percentage of nickel (austenitic nickel steels) have excellent corrosion-resisting properties and resistance to oxidation at elevated temperatures, and are practically non-magnetic.

(*Bureau of Information on Nickel.*)

Effect of Chromium in Steel.

Chromium differs from that of nickel in that it forms a double carbide, resulting in greater strength and hardness in a heat-treated steel. By the use of nickel and chromium, the nickel strengthens the ferrite matrix and the chromium strengthens the carbide constituent, giving superior physical properties than when either element is used alone. The presence of nickel and chromium ensures considerable hardening, with a rate of cooling through the critical range slower than that permissible in the case of a steel with a similar content of either element. This makes nickel-chrome steels especially suited for large sections requiring heat-treatment; giving them deep and uniform hardening power. In carbon steel chromium raises fairly uniformly both the Ac_1 and Ac_3 points. In nickel steel, however, the effect is somewhat different. The Ac_1 point in uniformly raised, but according to available data the Ac_3 point, when the carbon is below ·3 per cent., seems to be actually lower than in a steel of equivalent nickel content, while with higher carbon the Ac_3 point is higher than in an equivalent steel.

Invar.*

Invar is a nickel steel containing about 36 per cent. nickel, together with about 0·5 per cent. each of carbon and manganese, with metallurgically negligible quantities of sulphur, phosphorus and other elements. It is made either in the open-hearth furnace or by the crucible method. It melts sharply at 1425° C. Above some 200° C. to its melting point, invar may be considered to consist of a homogeneous solid solution of iron, nickel and carbon. Below 200° C. and at a temperature dependent on its history and exact composition it undergoes a reversible transformation of such a nature that for any sample the transformation may be incomplete. This condition of thermo-chemical instability gives rise to both slowly changing and quickly changing values of its physical properties—changes which are particularly manifested in the expansion.

Invar can be forged, rolled, turned, filed and drawn into wires, and it takes a beautiful polish, giving an excellent surface on which fine lines may be ruled. In general it should be worked slowly. It will withstand without spotting the corrosive action of water. Its density is about 8·0 grm. per cm.^{3}, its electrical resistivity is of the order of 80 microhm per cm., or about eight times that of pure iron, and its temperature coefficient of electrical resistance about 0·0012 per degree centigrade. It is ferromagnetic, but becomes paramagnetic in the neighbourhood of 165° C.

The mean coefficient of linear expansion between 0 and 40° C. is in the order of one millionth for the ordinary invar, and samples have been prepared with even small negative coefficients; the amounts of carbon and manganese present appear to exercise considerable influence on the expansion. Above 200° C. the expansion of invar is approximately that of Bessemer steel.

Invar is subject to changes in length due to 'after effects' following cooling from a high temperature, and to changes in length following even slight alterations in temperature. Invar also gradually elongates with time, forged and drawn material behaving somewhat differently in this respect, so that there is a determinable, seasonal correction to be applied to its length when used as a length standard. It also shows marked magnetostriction phenomena or changes of length accompanying changes in strong magnetic fields.

Mechanical properties: Tensile strength, 22·5–36 tons per sq. in.; elastic limit, 3·1–13·5 tons per sq. in.; elongation, 40–50 per cent.; reduction of area, 40–65 per cent.; Brinell hardness, 160; scleroscope hardness, 19; modulus of elasticity, 22,500,000 lbs. per sq. in.

Cobaltron Steel Alloy (Patent).

This alloy (patent) introduced by Messrs. Darwin and Milner, of Sheffield, is made by adding cobalt to chromium-carbon steel. The maximum temperature necessary for the hardening is 1000° C. (tungsten steel requires from 1250° to 1350° for the best results) and hardening is said to be satisfactory when the steel is allowed to cool naturally in still air. Analysis of cobaltron shows that the following elements approximate to the amounts stated below:—

Carbon	About 1·5 per cent.	Molybdenum	About 1·25 per cent.
Cobalt	,, 2·25 ,,	Tungsten	,, 0·25 ,,
Chromium	,, 11·0 ,,		

'Heenan' Patent Oil Coolers for Heat Treatment of Steel.

The continuous introduction of hot steel into oil quenching tanks naturally heats up the oil, which retains heat for a long time, and rapidly becomes too hot to permit of the process being carried on.

Owing to the poor heat conductivity of oil, such arrangements as water-jacketing the tank or inserting pipe coils through which water is circulated are ineffective, the cool surfaces affecting only that portion of the oil in immediate contact therewith, while allowing the main body to remain over-heated.

The 'Heenan' system of oil cooling is to extract the hot oil by means of a suitable centrifugal pump, and pass it through a 'Heenan' oil cooler before returning it to the quenching tank. This oil cooler is built up on lines similar to those of the water cooler described on p. 1232. In effect, oil is spread over a large cooling surface with which cool air from the surrounding atmosphere is then drawn into contact. Circulating water is not used.

This machine has been applied amongst other purposes to quenching processes in connection with the hardening and tempering of gun tubes, rifle barrels, steel tools, gear wheels, springs, aeroplane engine parts, etc.

Chromium Plating of Steel.

Using solutions of 3 grams per litre chromium sulphate and 200–400 grams per litre chromic acid, good adherent deposits of chromium on iron can be obtained. The cathode current density range for good deposits should be from 100–150 amperes per sq. ft.

Best results are obtained using Sargent's solution of 3 grams per litre chromium sulphate, 245 grams per litre chromic acid, and a current density of 125 amperes per sq. ft., the anodes being of chromium.

Chromium-plated iron and steel have a hard, bright, silver-like surface, resist atmospheric corrosion indefinitely, and are resistant to the action of fumes of nitric acid, hydrogen sulphide, and ammonia. They also resist the corrosive action of molten tin, zinc, and brass. Steel does not lose its temper during chromium plating.

(See also p. 2719.) (*Chemical and Metallurgical Engineering, April* 21, 1924.)

CASE-HARDENING.

The case-hardening of steel is dependent upon the fact that above certain temperatures the affinity of iron for carbon is so great that when iron or steel is heated at these temperatures in contact with suitably chosen carbonaceous materials ready absorption of carbon supervenes. The quantity of carbon that can be absorbed by iron or steel under the above conditions varies according to the following factors—

1. The composition of the iron or steel.
2. The temperature at which the process is conducted.
3. The length of time during which the process is continued.
4. The nature of the carburising material.

The Composition of the Iron or Steel.

Case-hardening, in the accepted sense, is rarely practised on steel containing more than 0·20 per cent. of carbon or 0·40 per cent. of manganese. The process is stated by Guillet to be hindered by the presence of nickel, silicon and aluminium, and hastened in the presence of manganese, tungsten, chromium, and molybdenum.

The Temperature at which the Process is Conducted.

The process is best conducted at temperatures above the critical range of the iron or steel treated. The usual temperatures for carburisation vary from 900° C. to 1000° C. The higher the temperature of carburisation the greater the rate of absorption of carbon and the deeper the effect of absorption.

The Length of Time during which the Process is Continued.

This factor can only be determined by experiment. It is generally considered that the best results are obtained when the carbon content of the surface layers of the case-hardened material are of eutectoid composition (about 0·90 per cent. C.).

The Nature of the Carburising Material.

The carburising material may be either solid, liquid, or gaseous. Solid materials are employed more generally than are liquid or gaseous materials.

Solid Case-hardening Materials.

For the purpose of obtaining deep 'cases' the articles to be hardened are packed in a suitably designed box with solid case-hardening substances or mixtures of substances, of which the following are examples :—

Charcoal (animal or wood).
Charred leather.
Crushed bone or horn.
Barium carbonate 40 per cent. and charcoal 60 per cent. (Caron's mixture)
Charcoal (wood) 95 per cent. and soda ash 5 per cent.
Charcoal (wood) 90 per cent. and common salt 10 per cent. (Guillet)

As case-hardening composition is bought by weight, and is required to fill up the case-hardening boxes, the specific gravity is an important consideration. The speed of conduction of heat through various depths of carburising material requires determining by experiment. A good case-hardening material should not diminish in volume appreciably during the carburising operation, and should be free from sulphur and phosphorus.

The box should be of plate iron not less than $\frac{1}{8}$ to $\frac{1}{4}$ inch thick. The lid of the box has two holes pierced in it for drawing testing-pieces out if required. For small articles a piece of wrought-iron tube, plugged or capped at one end, may be used ; the other end is closed by a second plug fastened with an iron pin passing through it and the pipe, the whole being luted with fine clay. The articles being previously finished, except polishing, are put into the box in alternate layers with the carburising mixture, commencing at the bottom of the box with carburising mixture to the thickness of about $\frac{1}{2}$ inch ; upon this a layer of the articles is placed, then another of carburising mixture about one-third the thickness of the first, and so on until the box is nearly full, finishing with carburising mixture about the thickness of the first layer, leaving room every way for the expansion of the articles by the heat, otherwise they will bend each other in the box. The packing completed, the lid is put on, the box luted and placed in a suitable furnace. The contents of the box require to be very gradually and uniformly heated to redness, and retained at this heat for the period required for the depth of caburisation desired. The depth of carburisation depends on the length of time the temperature is kept up. For testing pieces plain pieces of the same kind of iron as the articles may be used. They require to be brightened, and are placed, at the time of the packing of the box, in the central part, in such a manner that they may be readily pulled out through the holes in the lid, either by a piece of iron wire attached or by being made long enough to project through the holes, so that they may be gripped with pliers ; the holes are luted the same as are the other parts. When the articles are sufficiently carburised the box is drawn from the fire, the lid taken off, and the contents are immersed in pure cold water : taken out when cold they are ready for polishing. To prevent rusting, the articles may be dried by riddling in a sieve with dry sawdust, after which they are wiped with a greasy cloth. If the articles be immersed in oil instead of water they will be much tougher but less hard, though sufficiently so for some purposes. It is not necessary to immerse them direct from the box, as it answers equally as well to allow them to remain in the box till cool, and then reheat them in an open fire and immerse them separately.

When the case-hardening is required to terminate at any particular part of the article, the part needed to be soft may be bound with iron wire and cased with loam. This prevents the iron from absorbing carbon at that part. The loam requires to be gradually dried on the article previous to putting in the box, otherwise it will crack. Another method is to cover the part needing protection with a copper tube (this is the most satisfactory method when the shape of the work will allow the use of the tube) or to paint it with a protecting paint (paint can be made from china clay and blacklead or from sodium silicate and sand). A frequent procedure is to carburise an object and allow it to cool in the box, finally machining off the carburised portion before quenching wherever it is desired to keep the surface soft. It is of course necessary to leave sufficient metal on the object before carburising in order to ensure complete removal of all carburised metal before quenching. With long objects, one end of which requires hardening while the other is to remain soft, it is possible to carburise the entire length, then reheat and quench one end only, allowing the other end to cool in air.

For the purpose of superficial case-hardening it is necessary only to heat the iron or steel to be treated to redness, to sprinkle one or other of the following finely powdered compounds or mixtures on the surfaces to be hardened, and to plunge the iron so treated into pure cold water. This method is simple and speedy, but the case obtained is insufficiently thick to resist much wear.

Potassium cyanide.
Potassium ferrocyanide.

Potassium ferrocyanide and potassium bichromate.

Sodium ferrocyanide 90 per cent. and anhydrous sodium carbonate 10 per cent.

Sodium ferrocyanide 80 per cent., anhydrous sodium carbonate 10 per cent., and potassium ferrocyanide 10 per cent.

Liquid Case-hardening Materials.

The immersion of steel articles in a bath of molten potassium cyanide (the fumes of which are of a highly poisonous nature) heated to 850° C. results in the formation of very hard but shallow cases.

Gaseous Case-hardening Materials.

The following gases have been employed for case-hardening iron and steel—illuminating gas, carbon monoxide, acetylene and petroleum vapour. All, according to Brearley, are supposed to be more effective if they are led through a solution containing ammonia, or otherwise are partly saturated with ammonia gas before entering the furnace. By increasing the pressure of the gaseous mixture it is possible to increase the rate of carburisation.

Rapid Case Hardening Methods.

One of the best is to instal a container for sodium cyanide and common salt mixed. These salts used molten are very efficacious, and many small parts can be thus cased without going to the trouble and expense of casing in boxes. The sodium cyanide needs careful handling, but it is a simple matter to arrange for it to be placed into the equivalent of a fume chamber, a place fitted with a fan so that an adequate draught will take away all the poisonous fumes.

The immersion of clean machined steel parts in the mixture will produce a reasonably deep case in the course of $\frac{1}{2}$ to 1 hour, and there is the additional advantage that the parts emerge from the bath quite clean and bright and can be quenched for hardening at once. Some trouble may be experienced in obtaining a suitable container for these molten salts, but the use of one of the nickel-chromium alloys will give excellent results.

Another good method of obtaining a reasonable case on steel consists simply of playing an oxy-acetylene flame on the steel, and a very few minutes at a temperature of 900–1,000° C. will produce an adequate depth of case. The flame must be suitably regulated so that there is no danger of the steel being cut, but an excess of acetylene in the flame will prevent this and will cause the casing to be formed much more quickly.

These methods are those by which small parts may be quickly hardened on their surface and are not intended to supplant the ordinary box carburising.

(*' Machinery,'* May 12, 1927.)

Thermal Treatment of Case-hardened Materials.

Quenching.—If the quenching takes place directly after the carburising operation, the resulting product is liable to possess a coarse structure in both the core and the case. In order to improve the structure it is better to allow the work to cool in the box after cementation, and then reheat it in a separate operation. The reheat may be made bare in the furnace, but with large objects which take long periods to obtain the desired temperature it is advisable to protect them from decarburisation by covering them with charcoal or old case-hardening mixture. This second reheat is most satisfactory at temperatures of about 780° to 820° C. It is claimed that very good results may be obtained by reheating twice, first with a view to refining the core and secondly to refine the case. A sample treatment of this description is :—

1. Carburise at 900° C. and allow to cool in box.
2. Reheat at 900° C. bare, and allow to cool in air.
3. Reheat bare for 20 minutes at 810° C. and quench in water.

Another common treatment which is said to yield fine core structures is to reheat twice and quench after each reheat, *e.g.* :—

1. Carburise at 920° C.
2. Reheat to 900° C. and quench in oil.
3. Reheat to 810° C. and quench in water.

In order to refine the cores of case-hardened articles it is advisable to heat the same to at least 875° C. (unless the carbon content of the core is above 0·20 per cent.) and quench. This treatment refines the core of the article but coarsens the case, hence it is necessary to reheat to a temperature somewhat above the critical range corresponding to the carbon content of the case (775° C. to 825° C.), subsequently quenching the article in water, or in oil.

Quenching in water results in a much more rapid cooling than oil quenching ; the former is necessary for ball races, cams, and all parts which have to be subjected to hard wear and require extreme hardness (80 to 90 scleroscope). Oil quenching of correctly carburised mild steel results in a hardness of 50 to 70 scleroscope. Small objects cool more rapidly, and therefore become harder than large objects undergoing the same treatment.

Tempering of the quenched articles still further improves the properties of the same.

'Nitride,' or Nitrogen Case-Hardening.

The process is based on the fact that certain steels will absorb nitrogen, and such steels undergo a eutectoidal transformation at 1,076° F., which enables an extremely hard non-brittle surface

to be produced. Steels containing 0·5–2·0 per cent. aluminium and 0·5–4·0 per cent. of an element, or combination of elements, having the properties of chromium are used. Ordinary carbon and alloy steels are not suitable.

TYPICAL ANALYSES OF STEEL 'NITRALLOY' (CENTRAL ALLOY STEEL CORPORATION, U.S.A.).

1,400	36·0	46·6	28·0	59·0	54	200
Annealed at 1,450	30·8	42·4	30·0	67·5	32	186

The nitriding process is carried out in a furnace (preferably electric), the temperature of which must be closely controlled around 950° F. The parts are placed in a gas-tight box provided with inlet and outlet tubes for the circulation of ammonia gas. No packing material is used, individual layers being separated by nickel wire netting. The rate of flow of gas is regulated by a needle valve on the ammonia cylinder, and this must be kept fairly constant during the entire cycle. The process takes from 2 to 90 hours, depending upon depth of case required.

Parts that require to be kept soft can be protected by tinning or other means.

Hardness of Case.—Readings taken with Herbert pendulum and converted into Brinell numbers.

Depth in Inches.	Brinell No.
0·000	1,002
0·005	999
0·010	810
0·015	516
0·020	434
0·025	378
0·030	378
0·035	351
0·040	351

Before the nitriding operation the parts should be heat-treated to impart the desired physical properties to the core. All strains set up by forging, etc., prior to nitriding must be thoroughly relieved by annealing at 1,000° F.

Annealing.

To Prevent Oxidation and Scaling during Annealing.

It is sometimes desirable that steel should be thoroughly annealed without any oxidation and scaling whatever taking place. The most popular method of doing this is to simply pack the stampings in sand, but this method is not good, because, unless the sand be extremely fine, air will eventually percolate through the grains of the sand. The following method has been found to give first-grade results, and steel articles may be heated for many hours and come out with a perfectly bright surface. The packing mixture consists of finely powdered burnt lime containing a trace of powdered charcoal. A thick layer of lime is tightly rammed down in the bottom of a box, similar to those used for case-hardening purposes. The articles are placed in position on the lime and a further layer of lime is tightly rammed down on top of them, with a sprinkling of powdered charcoal on top of the lime. Several layers of articles may be packed in this way till the box is full, when it is covered with a lid and luted up with clay. Although this process is not so quickly performed as some, it gives excellent results.

If such articles as small die castings or brass or bronze extruded sections require to be annealed, the articles are dipped in a saturated solution of borax or boric acid in methylated spirit. The spirit evaporates at once, and leaves a sound protective coating of the solid which coagulates on heating and effectively resists the deleterious action of oxidising and other gases at temperatures up to some 750 deg. C., which is as high a temperature as is usually employed for the general heat-treatment of non-ferrous metals and alloys.

The coating of the borax or boric acid is so extremely thin that there is usually no necessity to remove it after heating, but should this be necessary, hot water will suffice.

(*Met.*, '*Machinery.*')

Corrosion of Metals.*

Corrosion of Iron.

Professor T. Turner in his book on 'Iron' says the results of the experiments of the Admiralty Committees which issued reports in 1877 and 1880 led to the conclusion that common iron was less affected by corrosion than best Yorkshire iron, which is in accordance with the statement of Gmelin that phosphorus diminishes corrosion in iron.

In these experiments :—

Common iron resisted corrosion better than Yorkshire iron 9·6 per cent.

Yorkshire iron resisted corrosion better than mild steel, 16 per cent.

In another series of experiments conducted by D. Phillips, in Cardigan Bay, and lasting for seven years, it was found that the average corrosion of mild steel during the whole period was 126 per cent. more than wrought iron.

The independent experiments conducted by T. Andrews also showed that wrought iron corroded less rapidly than mild steel when the cleaned metallic surfaces were exposed to the action of the water.

Iron rusts very quickly when immersed in water from bogs and marshes which contain a large quantity of carbonic acid, derived from decayed vegetable matter.

Iron does not rust in dry air.

Iron subject to vibration rusts slowly. Railway rails in running roads where trains are passing frequently rust much less than those in sidings which are little used. Rails which are kept in reserve and not in use rust more quickly still.

Thin iron rusts more rapidly than thick, because the expansion and contraction owing to changes of temperature throws off the scales more quickly.

In moist air, steel rusts more rapidly than wrought iron, and wrought rusts more rapidly than cast. (See table, p. 174.)

Cast iron in salt water becomes in time soft and porous. The smoother the surface of iron the more slowly it rusts.

Once rust forms the process goes on more rapidly; rust being a porous substance it absorbs moisture and acids from the atmosphere.

Protection of Iron from Rust.

The types of coating applied to iron and steel for their protection may be classified as follows :—

1. Adherent coatings. 2. Compound coatings.

1. Adherent Coatings.

These may be metallic or non-metallic in character. Of methods for the production of metallic coatings of this type the following are the most noteworthy examples :—

---

* See also p. 174.

(*a*) *Galvanising.*—This is a process which has for its object the coating of the material with zinc. Two processes, known respectively as hot galvanising and electro-galvanising, are employed for attaining the desired object.

Hot galvanising consists in the immersion of the object to be protected from corrosion in molten zinc or spelter, the surface of which is largely protected from oxidation by a supernatant layer of ammonium chloride. Modifications of the simple process briefly described in the last sentence are known under the following names, Winiwarter's process, Kufler's process, Bedson's process, Reese's process, Porter's process, etc.

The amount of zinc on modern galvanised sheets varies from 1 to 2·5 oz. per square foot coated. The coating generally contains from 0·25 to 1·00 per cent. of lead and from 2 to 6 per cent. of iron.

The most obvious disadvantages of galvanising are two in number: first, the iron or steel coated has to be raised in temperature for the desired effect to be attained; second, a layer of weak zinc-iron alloy forms at some point intermediate between the true zinc layer and the iron or steel upon which it is designed to rest. This thin lamina of weak alloy, mainly the compound $FeZn_7$, may be insufficient in a majority of cases to cause trouble, but a serious reduction in tensile strength is frequently brought about as a result of the presence of this weak material in fine gauge wires and sheets.

Electro-galvanising (cold galvanising) consists in the deposition of zinc electrolytically upon the object to be protected from corrosion, a soluble zinc salt being employed as electrolyte. The most important process under this head is that of S. Cowper-Coles, wherein an electrolyte of zinc sulphate is used, the electrolyte being continuously regenerated by circulation through tanks containing zinc dust. The methods of cold galvanising associated with the names of Heathfield, Powick, Pettkoff, Rawson, Wagner, Walker, etc., are worthy of note. Particulars of their processes are obtainable in the technical press.

The electrolytic process leads to the formation of an intermediate lamina of only minute thickness. In this particular the coating produced by the electrolytic process is an improvement upon that obtaining as a result of hot galvanising. It is, however, porous, and in this respect is inferior to the zinc coating produced in the dipping process. No marked superiority can be claimed for either of the processes.

Electro-galvanising has made great progress during the past few years, and may now be regarded as an efficient method of rustproofing. By its means a wide range of articles may be coated with a film of zinc which, while ample to protect from oxidation, does not affect ductility or tensile strength. The fact that perfect cleanliness must be achieved before the adherence of zinc can take place prevents dirty patches on the article becoming coated. The main cause of failure with hot galvanised work is the covering up, through the surface tension of molten spelter, of dirty or scaly places, which blister or otherwise fail in a comparatively short time. A commercially protective coating is obtained with a deposit of 4 oz. per square yard of surface. The deposit is practically pure, lead being the chief adulterant, then only in a fraction per cent. Accurately machined parts can be assembled after coating, this overcoming a difficulty ever present in the past. Hot galvanised bolts must have the thread bared before the nut will fit. Cold galvanising coats the thread so that the configuration is not destroyed, and unless the nut is a very tight fit the zinc remains on the thread and thus protects it against corrosion.

Admiralty specifications require a deposit of 0·86 oz. of electro-deposited zinc per sq. foot of surface of the articles treated.

(*b*) *Tin plating* is a process similar to hot galvanising, tin being the coating metal. The protection afforded to iron and steel by tin is less effective than is that of zinc.

(*c*) *Terne plating* consists of the coating of the material to be protected with an alloy of lead containing from 50 to 75 per cent. of tin (generally 70 per cent. tin).

(*d*) *Lohmanising*—in this process the metals to be protected are (i) pickled in an acid bath, (ii) dipped into a salt bath which deposits a metallic salt over the entire surface of the body, (iii) immersed in a bath of molten alloy of zinc, lead and tin heated to a temperature of from 500 to 600° C. The composition of the tin-lead-zinc alloy is varied to suit the material being treated.

(*e*) *Electro-plating*—the coating of iron and steel electrolytically with copper, nickel, etc., is well known.

(*f*) *Copper 'clothing'*—the casting of copper round or the welding of copper to steel and the rolling of the resultant material to the required shape and dimensions has been practised, e.g. Monnot process, Willis process, etc. (vide *Iron Trade Review*, vol. li. 479).

(*g*) *Nickel 'clothing'*—processes similar to the Monnot and Willis processes have been successfully applied to the coating of iron and steel with nickel and cupro-nickel.

(*h*) *Metallic spraying*—the application of liquid metal in finely subdivided form by a spraying machine has been accomplished by M. U. Schoop, whose process, 'the Schoop process,' allows of the coating of iron or steel with an adherent layer of tin, lead or zinc, the material being coated remaining meanwhile at the ordinary temperature. The material under treatment must be scrupulously clean if adhesion of the finely-divided spray is to be perfected (vide *Metal Industry*, vol. xvi. 41).

2. Compound Coatings.

The term 'compound' is applied here to such protective coatings as are produced by chemical action, the ultimate result of which is the formation of a chemical compound, such, for example, as magnetic oxide of iron (Fe_3O_4), iron-zinc ($FeZn_2$), etc. The compounds formed may be, as already noted, either chemical (in the general sense of the term) or intermetallic (in the specialised sense of the term).

Chemical Compounds.

Barff's process consists in passing superheated steam over the objects, which are heated in an air-tight retort to about 260° C.; for the formation of a more perfect protective coating higher temperatures are necessary (650° C.). Articles so treated are said to be 'barffed.' Relatively small objects only can be treated as above. The coating formed consists of the mixed oxides of iron (Fe_2O_3 and Fe_3O_4).

The *Bower-Barff* process is an improvement on the above, and consists in the heating of the objects to be protected to about 900° C., at the attainment of which temperature superheated steam is introduced to the same, which has the effect of producing a coating of the mixed oxide already referred to. This operation having continued for about twenty minutes, carbon monoxide is injected into the retort for a period of from fifteen to twenty-five minutes, during which time the entire reduction of the coating to the condition of magnetic oxide of iron is completed.

The *Gesner process* treats iron and steel at a moderately high temperature (550° C. to 650° C.) in a retort whereinto may be introduced an atmosphere of steam. The preliminary heating occupies twenty minutes; the steam is then allowed to react with the oxide formed in the first operation for about half an hour, when naphtha is introduced and allowed to remain in contact with the material under treatment for about ten minutes. Finally, steam is again introduced. The whole sequence of operations occupies about one hour and twenty minutes.

The *Parker 'dry' process.*—Under a patent assigned to the Parker Rust-proof Company, of Detroit, the formation of an adherent coating of oxide may be obtained by first heating the objects to be treated to about 600° F. and then subjecting them to fumes of the acid metaphosphates of strontium, molybdenum, and tungsten.

The *Hans Renold process.*—Remove all grease or oil from the articles to be treated by suspending in a bath of hot lyco (11 oz. per gal.) for about three minutes, wash in cold running water for a few seconds, then suspend from cathode brass bars by steel hooks in an electrolytic bath (KCN, 98 per cent. pure, 4 oz. per gal. of water), iron plates forming the anodes. Leave here for five minutes, and when a current of 25 amps. at 8–10 volts is passed through the bath all foreign matter on the surface will be removed. Wash off the cyanide by means of hot water to facilitate drying.

Heat the articles to 700° C., then quench in cotton-seed oil by immersing in the main body of the quenching tank for seven or eight seconds before allowing to fall to the bottom.

Dry by heated sawdust and hot-air blast (dried and filtered by passing through calcium chloride and cotton wool).

Insufficient oxidation results in the finished bodies having a grey appearance, due to the atmosphere of the furnace containing too much gas. Blistering is due to overheating.

Villon's process consists in subjecting the iron or steel to be protected to the vapour of sulphur as a result of which treatment the monosulphide of iron is found.

The *Bertand process* requires that the articles to be treated be thoroughly cleaned by sand-blasting or similar means before they are immersed in a bath, such as will lead to the deposition of copper upon the same as a result of reaction between the iron and a suitable electrolyte. The deposition may be achieved by the application of electricity or by more purely chemical means. After thorough washing the articles are heated in an oxidising atmosphere to a temperature of about 600° C., which treatment leads to the formation of a fairly adherent coating of magnetic oxide of iron.

The *De Meictin's process* depends upon the formation of a coating of magnetic oxide (Fe_3O_4) upon iron or steel which is placed as the positive pole in a bath of distilled water, maintained at a temperature of from 70° C. to 80° C., a current of electricity being passed through it. The oxide coating is adherent, provided the current density is not over great, and may be rubbed and polished. This method is of value in the treatment of such articles as cannot be submitted to any processes which might tend to temper or anneal the objects under treatment.

The *Parker 'wet' process* (patent) consists in the immersion of the iron or steel to be protected in a bath of a 1½ per cent. solution of the acid metaphosphates of tungsten, molybdenum, or any of the metals of the third, fourth or fifth group of elements.

The *Coslett process* (*Coslettising*).—Cast iron or steel articles treated by this process are not only rendered rust-proof but improved in appearance.

The articles to be treated should be perfectly clean and free from tin, nickel, or grease.

The best results are obtained on a frosted surface, such as is left by sand-blasting or pickling. Sand-blasting is to be preferred, as any traces of acid render the treatment ineffectual.

The coslettising bath is prepared by heating in a cast-iron or welded steel tank a sufficient quantity of distilled water to easily cover the articles to be treated. When boiling add for every gallon of water in the bath (1) two ounces of phosphoric acid (syrupy sp. gr. 1·5); (2) one ounce of iron filings. This should be carried out in the open or under an uptake, as the reaction results in the formation of disagreeable fumes. When this reaction has ceased the bath is ready for use.

The articles should be placed in the bath as soon as possible after sand-blasting, and should be gently boiled for two hours.

A second tank should be prepared containing distilled water, which should be heated in time to wash the articles as taken from the coslettising bath.

At the expiration of the specified time the articles should be taken from the coslettising bath and placed directly into the hot water and thoroughly scrubbed with a stiff bristle brush.

They may then be dried off, and if heavy will dry quickly themselves, but if light should be placed in an externally heated oven.

As soon as dry and while warm they should be dipped in a mixture of lubricating oil and turps substitute, in the proportion of 2 to 1, and left to drain. When cold, surplus oil may be removed with clean waste or wiper.

To allow for evaporation of bath a mixture similar to that in the bath should be made up and added as required.

To keep the bath at the correct strength it is necessary to titrate a sample of the bath with $\frac{1}{10}$ normal sodium hydrate. To make this test, 10 c.c. of the bath should be placed in a conical flask, a few drops of phenolphthalein solution being introduced as an indicator. The $\frac{1}{10}$ normal sodium hydrate should be added from a burette, until a permanent pink tinge is given to the liquid in the flask. The amount of sodium hydrate dropped into the flask should be noted, and if the bath is correct this amount will be 10 c.c. If more sodium hydrate is used, the bath is too strong and will require diluting with distilled water; if less is used, the bath is weak and will require the addition of phosphoric acid and iron filings in the given proportion.

The appearance of the deposit obtained on the article is a rough guide to the state of the bath. The proper deposit is of a uniform dull black colour, but if the bath is too strong this black coat is covered with a pearly white deposit which will not scrub off. If the bath is too weak the articles appear unevenly covered with a thin grey coat.

It is stated that in the present coslettising process (which cannot be used except under licence from the Coslett Anti-Rust Syndicate) phosphorised zinc, made under special conditions, is used instead of phosphorised iron, the solution otherwise being prepared in much the same manner. This newer process is said to give much better results, and the depth to which the articles are rust-proofed to be considerably greater.

The need for the absolute cleanliness of the articles before treatment cannot be too strongly emphasised, and they should not be handled after cleaning, or before they are finally oiled.

Intermetallic Compounds.

Sherardising.—The articles to be coated are first cleaned and dipped in an acid bath as for galvanising; they are then put in a suitable retort which is, if possible, airtight, and are surrounded with ' blue powder '; the retort is then raised to a temperature of 500° or 600° F.

If the retort cannot be made airtight, about 3 per cent. of finely powdered carbon should be mixed with the zinc to prevent the formation of zinc oxide.

The heat is kept up for a few hours, after which it is allowed to gradually decrease.

A coating is formed which consists mainly of an intermetallic compound of zinc and iron ($FeZn_3$).

Calorising.—A somewhat similar process to the above, in which aluminium powder is utilised as the agent and wherein the resultant protective coating consists chiefly of an intermetallic compound of iron and aluminium.

Stainless Steel.

Stainless steel or rustless iron are not altogether stainless or rustless under all conditions. Moreover, the ' rustless iron ' is really a dead-mild steel containing a certain percentage of chromium, which gives the steel its corrosion resisting properties. Mild stainless steel contains about 11 to 14 per cent. chromium, with 0·1 per cent. carbon and under, the other constituents, silicon, sulphur, phosphorus, and manganese, being all more or less in normal percentages. (Apparently when the cast contains 0·1 per cent. and less of carbon it is called ' rustless iron, and above that percentage ' rustless steel.')

One of the valuable properties of mild stainless steel is its behaviour at high temperatures. When pieces of the material which have been polished are heated up gradually, temper colours

appear on the surface similar to those obtained when ordinary carbon steels are heated up, but in the case of mild stainless steel these temper colours appear at much higher temperatures, as shown by the following table:

Colour.	Mild Stainless Steel.	Ordinary Steel.
	° C.	° C.
Pale straw	290	225
Straw	340	235
Brown purple	390	265
Purple	450	280
Bright blue	530	290
Dark blue	600	315

Up to temperatures of about 825° C., mild stainless steel resists scaling to a remarkable degree, but above this temperature the material begins to scale to some extent.

Hot Rolling and Forging of Mild Stainless Steel.

The most suitable hot rolling temperature for this material is 1050° C. to 1100° C., and it is essential that for rolling and forging the material should be brought up slowly to about 900° C. and then slightly quicker to the rolling and forging temperature. It should be allowed to soak for a long period to ensure a uniform temperature through and through.

For forging, it should be worked quickly and with rapid blows between the temperatures of 1150° C. and 900° C. Below 900° C. to 850° C. it is not so easily deformed, and if any heavy work is put on the material after it has fallen below these temperatures it is very apt to be badly stressed or burst.

For drop stamping, it is advisable to work at a slightly higher temperature, and all stampings must be trimmed while hot, or annealed before trimming on account of the air hardening properties of the steel. Otherwise, if an attempt to trim is made, cracking and splitting will occur, as well as damage to tools.

Annealing.

The critical range of mild stainless steel runs from about 865° C. to 965° C.

To anneal mild stainless steel to obtain the maximum softness, it should be heated up slowly to about 1000° C. and held at this temperature for a period of time in proportion to the mass of metal, and then allowed to cool off slowly in the furnace, making sure that no currents of cold air enter the furnace.

Although steel annealed this way has the maximum degree of softness, it is not in the best condition for machining. The steel in this state is very soft and tough, and so drags and tears when machined, leaving a very rough surface.

To soften the material for good machining properties or cold drawing and cold rolling, it is best to anneal at 750° C. to 800° C., preferably about 780° C., and then to cool in the furnace or draw and cool in the open air.

Mild stainless steel has distinct air hardening properties, so that it should always be annealed or high temperature drawn at 750° C. to 800° C. as stated above, after it has cooled down from a hot rolling or forging temperature, before it can be successfully machined or cold worked.

Cold Rolling and Drawing.

The material will cold roll, cold draw and deep draw, or press very well, but owing to the percentage of chromium in the metal, the depth of each draw, when the steel is being deep pressed or drawn, obtained at each operation is only about half that got when working on mild steel, before the material must be annealed.

In cold rolling and cold drawing, the reduction of one gauge at a pass can be used, but it is found necessary to anneal after every second or third pass.

As with all materials, a distorted surface is always more liable to rust, and the same applies to mild stainless steel, especially if the surface happens to be unevenly distorted.

In cold working, strains are always set up in the material, and sometimes strained parts are not confined to the surface where they can be ground off, but are inherent in the steel and the strains must be removed by heat treatment. These strains are not only liable to cause rust, but are apt to cause the steel to crack if put into service. It is thus evident that it is advisable to anneal or high temperature draw at 780° C. all material which has been cold worked in any way.

Pickling.

The proper pickling of mild stainless steel is a very important factor in the manufacture of articles of this material. If the steel is left coated with scale, or has small pieces of scale left on the surface it will rust wherever the scale is present. It is therefore essential that the finished surface should be free from all scale, roakes, seams, pits, or cracks, or even stamp marks, as otherwise rusting will result.

The acid pickling baths generally used for this material are as follows:

1. 50 per cent. solution of hydrochloric acid used hot at 60° C. to 70° C.
2. 15 per cent. solution of sulphuric acid used hot at 60° C. to 70° C.
3. Ten minutes in a 50 per cent. commercial hydrochloric acid, then transfer without washing to 20 per cent. nitric acid for 25 minutes, both these solutions being worked cold.

Of these acid pickling solutions, No. 3 is the one which has given the most satisfactory results. Other methods which have been used for cleaning this steel are electrolytic pickling in an alkaline bath, which has been more or less successful for bars, etc., and articles of simple shape. Acid pickles containing chemical salts to accelerate the action, have also been used with considerable success.

Grinding.

The grinding of mild stainless steel must be carried out very carefully, as this material is more difficult to grind than ordinary steel. This metal dissipates heat very slowly, and great care should be taken in grinding in order that grinders' 'scorch' is not produced. Grinders' 'scorch' is due to harsh grinding and produces a brownish discoloration on the steel. This discoloration is really a temper colour produced by the heat generated on the surface of the work, and will cause rusting, due to the local distortion set up. Wet grinding is much better than dry grinding.

Etching.

In etching mild stainless steel, the following solutions have given very good results:

1. A saturated solution of ferric chloride in hydrochloric acid to which a little nitric acid has been added. This solution is used full strength.
2. A mixture of hydrochloric acid and nitric acid in the proportion of three to one and used full strength after allowing to stand for about 24 hours.
3. A saturated solution of copper sulphate in hydrochloric acid. This solution is used for light etching.

Physical Properties.

The physical properties obtained from mild stainless steel in the annealed condition, and also in the hardened and tempered state, cover a very wide range; this will be seen from the following table:

TESTS OF TEMPERED BARS.

Tempered at.	Yield Point. Tons per sq. in.	Tensile Strength. Tons per sq. in.	Elongation. Per Cent.	Reduction of Area. Per Cent.	Izod Impact. Ft. lbs.	Brinell Hardness. Kg. per sq. mm.
° C.						
200	66·5	73·0	12·0	37·5	35	340
300	66·0	72·5	12·5	37·0	39	332
400	65·5	72·3	16·0	50·0	38	332
500	59·0	72·5	18·0	52·0	36	340
600	38·0	48·0	22·5	62·0	66	235
700	31·0	41·0	27·0	66·0	80	192
750	28·0	36·6	30·0	69·0	88	174

These tests were made on 'as rolled' and 'annealed' bars quenched from 950° C. in oil and tempered at various temperatures.

Welding.

Mild stainless steel can be welded by either the electrical process or by the oxy-acetylene method. It will not weld by the usual method of heating in a smiths' fire.

In welding, the temperature of the metal at the weld is raised to a fairly high temperature, so that the material on cooling down will air harden and should be annealed before any turning, grinding, or polishing is done.

(*H. S. Primrose, A.M.Mech.E., M.Inst. Met., Paper read before the Manchester Association of Engineers, Friday, December* 19, 1924.)

HARDNESS OF STAINLESS STEEL AT ELEVATED TEMPERATURES.

(*Hadfield.*)

STAINLESS IRON.

Stainless iron is produced in the basic-lined electric furnace. Owing to its greater softness it forges more easily than the harder varieties of stainless material; it works probably as easily as a 40 carbon steel, and hence may be forged, rolled, or drop stamped. Stainless iron does not air-harden so intensively as the higher carbon varieties. It does air-harden, but the degree of hardness is considerably less, being in the range 280–380 Brinell instead of 450–550, as obtained with a stainless steel with 0·3 carbon.

PHYSICAL PROPERTIES OF STAINLESS IRON. ONE-IN. BAR. OIL-HARDENED, 930° C.

Tempered at ° C.	Ultimate Strength. Tons per sq. in.	Yield Point. Tons per sq. in.	Elongation. %	Reduction of Area. %	Impact. Ft./lbs.

800	56	33	13·0	38	37
Annealed	35	21	37·0	68	80

It may be readily cold-worked, and provided the amount of distortion produced is not too great, the resistance to corrosion is not seriously affected. It can be drawn into wire and tubes. The general character of the resistance of stainless iron to various corroding media is similar to that of stainless steel. It is attacked readily by hydrochloric, sulphuric, and sulphurous acids. It is practically unaffected by saturated or superheated steam, lubricating oils, petrol, benzol, paraffin, greases, etc. It resists oxidation well at elevated temperatures. At temperatures up to 700°–750° C. a series of temper colours are produced, similar to those obtained on ordinary steel, but at much higher temperatures. Above 700°–750° C. up to about 825° C. a polished surface becomes covered with a grey film without, however, losing its polished appearance, and the specimen neither gains nor loses weight appreciably. Above 825° C. it begins to scale appreciably.

(*Monypenny.*)

Heat-Resisting, Non-Corrosive Steels ('Enduro Nirosta').—These steels are austenitic and non-magnetic, and cannot be hardened by heat-treatment, any increased hardness being produced by cold-working. Heat-treatment necessary to put steel in a condition to resist corrosive attack and to restore softness, ductility, and machinability:—Heat quickly to 2,100°–2,150° F., cool rapidly in air or water, depending on section. Do not soak in furnace. For forging, heat slowly to 1,500° F. and soak, heat rapidly to 2,100° F. without soaking.

This material is suitable for all classes of work, including deep drawing. Having the ductility of copper it can be drawn into fine wire.

Average Analysis.—Carbon under 0·16, manganese under 0·5, silicon over 0·5, chromium 17–20, nickel 7–10, phosphorus and sulphur 0·25 max.

COPPER.

Copper containing at least 99·95 per cent. of the pure element is produced on a commercial scale in large quantities. The average tenacity of cast copper is about 10 tons per square inch, that of worked copper is about 15 tons per square inch, while Roberts-Austen quotes the following figures for the mechanical properties of slowly annealed, hammered, rolled bars of copper of a high degree of purity :—

Elastic limit	1·16 tons per sq. in.
Maximum stress	13·47 „
Elongation	37·0 per cent.
Reduction of area	61·0 „

Impurities in Commercial Copper.

Arsenic increases the hardness and the tenacity of copper. When present in moderate quantities it increases the percentage elongation of the metal. It improves the rigidity and strength of copper at high temperatures, hence, for fire-box plates, the use of copper containing from 0·3 per cent. to 0·5 per cent. of arsenic is frequently specified. In copper that is to be employed in the manufacture of brass subsequently to be cold-worked, not more than 0·05 per cent. of arsenic should be allowed.

Antimony is similar in action to arsenic, but it should be limited to traces in such copper as is to be used for the manufacture of brass that is to be cold-worked.

Bismuth being the most deleterious element that can be present in copper, owing to its tendency to induce red-shortness, not more than traces of this element should be allowed.

Iron is rarely present in copper in more than traces.

Lead is, after bismuth, the most objectionable impurity likely to be present in copper, although it is of value in metal that is to be rolled into sheets, on account of its softening effect on copper. Not more than the smallest quantities of this element should be allowed in copper for cold-worked brass.

Nickel hardens copper, but is in no way deleterious when present in such amounts as are usual in commercial copper.

Oxygen in small quantity does not have any very radical effect on the mechanical properties of copper. It is important in bringing copper up to the 'pitch,' and in combining with deleterious impurities to form insoluble and infusible compounds, thus separating and distributing these impurities and rendering them harmless.

Sulphur tends to embrittle copper, but is rarely present in refined copper.

Tellurium is similar to sulphur in its action on copper.

Silver, tin, and zinc are sometimes present in copper, but are rarely present in such quantity as to have much effect on the metal.

It has been found practically impossible to cast copper which is mechanically sound and of high electrical conductivity, on account of the porous metal that is obtained. By an addition of boron this can be accomplished. One per cent. of boron suboxide flux—equivalent to 0·08 to 0·1 per cent. of boron suboxide—is added to the copper, and a casting that is commercially sound is obtained.

ZINC.

Zinc is marketed in two forms—as sheet zinc (see Sheet Zinc Trade Gauge, page 11) and as spelter, *i.e.* flat rectangular ingots from 1 to 2 inches in thickness. The tenacity of zinc as cast is about 1 ton per square inch, and its elongation is practically nil. Zinc, after compression under a stress of 20 tons per square inch at 100° C., has a tenacity of about 11 tons per square inch.

It is ductile between 212° F. and 302° F. and can then be shaped as required. But when either above or below these limits it becomes brittle and unpliant, and therefore not adapted for treatment. It melts at about 786° F. if volatilisation is guarded against.

Impurities in Commercial Zinc.

Arsenic is a common impurity in spelter. It does not occur in such quantity as to have a deleterious effect upon the mechanical properties of spelter or of such alloys as contain it. It is, however, an objectionable ingredient in such zinc as is to be employed in the production of hydrogen.

Cadmium is nearly always present in zinc; in electrolytic varieties of the metal it rarely exceeds 0·07 per cent., in other varieties as much as 0·40 per cent. is found. The effect of this element is to harden spelter and to make it more brittle. Cadmium is, on this account, objectionable when the zinc has to be rolled into sheet or to be used for galvanising telegraph wires. In zinc for the manufacture of brass subsequently to be cold-worked as much as 0·20 per cent. of cadmium may safely be allowed.

Copper tends to harden zinc, but is rarely present in quantity sufficient to effect radical change in the metal.

Iron hardens and embrittles zinc. Its presence tends to the formation of dross in the galvanising process.

Such zinc as is to be used in the manufacture of cold-worked brass should not contain above 0·10 per cent. of iron. Electrolytic spelters rarely contain above 0·025 per cent.; as much as 2·5 per cent. of iron is, however, to be found in certain zincs.

Lead is present in certain brands of zinc up to 2·5 per cent. The purer brands of spelter contain up to 0·20 per cent. of lead. The presence of lead is not deleterious where the spelter containing it is to be used for general brass manufacture, but where brass is to be cold-worked or specially treated care must be taken that the spelter used has not too high a content of lead.

Lead in moderate quantity tends to make zinc softer in rolling. When present in quantities in excess of 0·7 per cent. it tends to the production of serious cracks in slush castings of zinc.

Other elements occasionally present in spelter in traces are sulphur and carbon.

TIN.

The London Metal Exchange form of contract (1911) for the purchase of tin recognises two classes of tin—Class A, tin assaying not less than 99·75 per cent. of pure metal; Class B, tin assaying not less than 99 per cent. of pure metal.

The tensile strength of cast tin varies (according to Thurston) from 2,000 to 6,000 lbs. per square inch. The elongation is, for all practical purposes, nil.

The principal impurities in commercial tin are lead, iron, copper, and arsenic. Sulphur, silver, bismuth, and antimony are of frequent occurrence.

NICKEL.

Nickel containing small quantities only of impurities is a commercial article. On account of its readiness to occlude carbon monoxide and other gases, and its affinity for carbon, it is difficult to obtain nickel in a pure state in the cast condition. Parker, experimenting on pure, dead soft, wrought nickel, has arrived at the following figures for the mechanical properties of nickel:—

Elastic limit	6–10 tons per sq. in.
Maximum stress . . .	18–20 „
Elongation . . .	8–15 per cent.

Nickel Plating.

According to the American Bureau of Standards, if nickel plating be made considerably thicker than is necessary or customary on brass parts, the protective value can be materially increased. It is believed that 0·001 in. is the minimum thickness that should be employed.

Impurities in Commercial Nickel.

Carbon is present in nickel up to 0·20 per cent., though it rarely exceeds 0·15 per cent. It has an embrittling effect on nickel when in the form of graphite, but when combined with nickel as nickel carbide it has a strengthening effect.

Cobalt has a strengthening and hardening effect on nickel, but in the quantities—up to 1·00 per cent.—usually found in commercial nickel, this element has but little effect.

Copper is similar to cobalt in its action, but rarely exceeds 0·20 per cent. in amount.

Arsenic should not exceed about 0·025 per cent. in such nickel as is to be subjected to cold-work, or in alloys for a similar purpose.

Iron has an effect on nickel similar to that of cobalt and chromium, but, being rarely present in quantities in excess of 0·75 per cent., its presence is scarcely noticeable.

As much as 0·30 per cent. of siliceous matter can be present in commercial nickel. Its effect on the properties of the nickel is uncertain.

Sulphur is occasionally noted in samples of nickel.

Nickel, if it is to be satisfactory for the manufacture of copper-nickel alloys for cold-working, should be free from all unreduced oxides.

CHROMIUM.

The colour of chromium is silver-white. Nickel has a little more of a yellow tinge to it than chromium. On the other hand, chromium will hold its colour indefinitely. Nickel will turn almost black in a laboratory atmosphere, and chromium will stay bright indefinitely. It is about the only metal known that will stay bright in a laboratory atmosphere. Not even platinum will stay as bright.

Electro-Deposition of Chromium.

In an article in the *Iron and Coal Trades Review* Mr. C. H. S. Tupholme gives the following hints on the electro-deposition of chromium. The cathode used was of iron, the bath at atmospheric temperature, and no mechanical stirring was used. In these conditions the most satisfactory concentration was obtained at 245 grammes per litre of chromic acid together with 3 grammes per litre of chromium sulphate. With this solution standardised the effect of varying the current density over the range between 2·7 and 54 amperes per sq. dm. or 25 to 500 amperes per square foot was tried, and it was found that good deposits were obtained up to 16 amperes per square dm. or 150 amperes per square foot. Beyond this current density the deposits were not so satisfactory, as the deposits were dark in colour and ultimately exhibited a tendency to crack. To obtain a bright deposit the most satisfactory current density was found to be between 100 and 125 amperes per square foot, using the electrolyte at ordinary atmospheric temperature.

ALUMINIUM.

For electrical conductors, and for a few special purposes, a grade of aluminium having a minimum purity of 99·5 per cent. is available. The lower grade, having a purity of about 99·2 per cent., is used for rolling into sheets for the manufacture of cooking utensils, chemical plant, etc. The impurities generally present in primary aluminium pig are: copper, iron, silicon, sodium, zinc, nitrogen, and a typical analysis of high purity aluminium is as follows:

Aluminium	99·5 per cent.
Iron	0·3 ,,
Silicon	0·2 ,,

The mechanical properties of cast aluminium are as follows:

Elastic limit	3–4 tons per sq. in.
Maximum stress	5–7 ,,
Elongation	3–4 per cent.

The tenacity of hard-rolled aluminium can be as high as 18 tons per square inch.

Primary aluminium is not used in the cast condition for constructional purposes. It is used as a deoxidiser in the manufacture of steel, and in the form of powder and dust in the thermit process and in paint. The principal use is in the wrought form, such as sheets, tubes, mouldings,

rods, wire, etc. As commercially pure aluminium has extensive application in the brewing and chemical industries, and also for domestic purposes, it is important to consider the action of acids upon it, which may be briefly stated as follows:

Hydrochloric Acid.—Attacked with great rapidity hot or cold and at all concentrations.

Hydrofluoric Acid.—Rapidly attacked.

Sulphuric Acid.—Attack slow with concentrated acid. Appreciably attacked with hot dilute acid.

Nitric Acid.—Attack very slow, the metal becoming passive (can be used for containers for cold strong HNO_3).

Acetic Acid.—Attack slow with cold acid, increases with use of temperature.

Lactic Acid.—Attacked very slowly (suitable for milk containers).

Oleic Acid.—Practically no effect.

Action of Air.—Attack very slow in fairly pure air, increases considerably in impure atmospheres. (The oxygen forms a thin film of oxide which tends to retard further action.)

Action of Alkalies.—Potassium and Sodium Hydroxide.—Rapidly attacked. Ammonium Hydroxide.—Attack slow. Alkaline Water.—Attacked appreciably by water in which alkalies or soap have been added.

Most metals will alloy with aluminium, but only a few definite alloys (aluminium—copper, iron, manganese, magnesium, nickel, silicon, tin, zinc) are used to a large extent. These include the binary alloys Al–Zn, Al–Cu, ternary alloys Al–Cu–Zn, Duralumin and related alloys, silicon and certain complex alloys. The so-called heavier alloys are the aluminium brasses and bronzes. Certain iron-aluminium bronzes and manganese-aluminium bronzes are also used.

Annealing Sheet Aluminium.

1. Prepare a mixture of ordinary whiting and oil, mixed to the consistency of thick paste. Coat the metal on both sides with this preparation, and place it on a clean fire or in a furnace, allowing it to remain until the oil in the paste becomes ignited. When this occurs withdraw the work from the furnace and allow it to cool gradually. The coat of whiting should then be removed from the surface of the metal by washing and brushing.

2. Heat the metal to a dull red colour, perceptible in the dark, and cool slowly. With this method care must be exercised to get an equal annealing temperature distributed over the entire surface of the work.

3. Heat the sheet aluminium until pine-wood sawdust just glows when sprinkled on it, which indicates a temperature of about 750° F. At this temperature a dry match-stick will just char when rubbed on the metal. (*A. Eyles*, '*Machinery*,' *Aug.* 11, 1921.)

The Protection of Aluminium from Corrosion.

Aluminium and its alloys can be efficiently protected against atmospheric corrosion under the most severe conditions only by the use of an enamel or varnish paint. Oil paints are very inferior in protective power to those referred to above.

MAGNESIUM.

Properties of Pure Magnesium.

NON-FERROUS ALLOYS.

COPPER AND ZINC.

The alloys of copper and zinc containing over 50 per cent. of copper are generally termed 'brasses.' The mechanical properties of these alloys have been the subject of numerous investigations; in this connection such authorities as Thurston, Charpy, Lohr Guillet, etc., should be consulted.

Below are given the results of Guillet's tests on the brasses. His tests were carried out upon material which was worked, then heated for ten minutes at 750° C. in a salt bath and finally cooled in air.

Alloy Composition.	Yield Point.	Max. Stress.	Elongation per cent. on 100 mm.	Hardness.

70 ,,	4·65	19·59	73·5	60/64
67 ,,	4·49	19·02	72·5	56/60
65 ,,	4·69	19·25	73·0	62
62 ,,	6·59	23·06	57·0	80/81
60 ,,	6·95	23·76	50·0	81/82
58 ,,	4·27	25·15	51·0	92/95
56 ,,	7·33	21·06	40·0	121/131

Figs. 13 and 14 (p. 2722) show the relation existing between the mechanical properties of the pure brasses and their copper content.

The casting temperatures of these alloys are of exceptional moment. The following tests show the influence of varying casting temperature on the tensile properties of 40·5 per cent. zinc-copper alloy castings poured from one crucible within a short interval of each other. Chemically the three castings were identical.

Casting Temperature °C.	Maximum Stress Tons per Square Inch.	Elongation per cent.
1,038	12·45	6·0
943	16·28	9·5
934	18·88	15·0

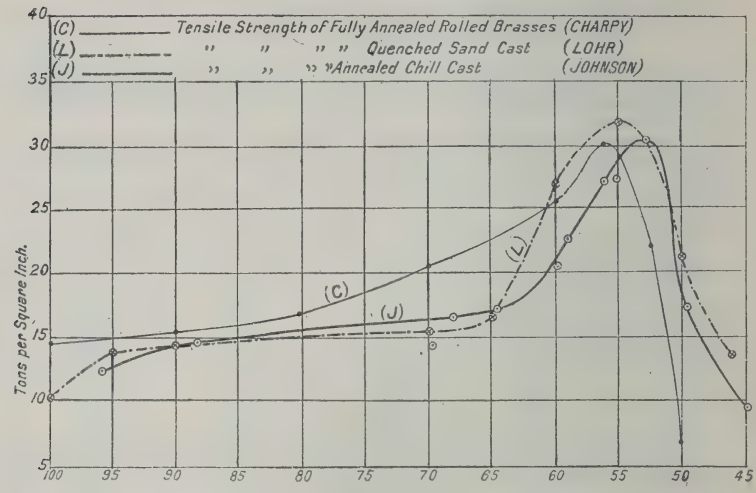
In every case with other alloys similar temperature variations have a similar effect on the mechanical properties. The following results obtained from manganese bronze were obtained by Guillemin :—

Casting Temperature °C.	Maximum Stress. Tons per Sq. In.	Elongation per cent.
1,400	15·2	13
1,300	19·7	45
1,250	21·6	35
1,200	22·9	30

In judging a suitable pouring temperature the appearance of the alloy in ladle or crucible may be used as a guide. With manganese bronzes this appearance is somewhat confused by the aluminium present, for, as is well known, this imparts a characteristic skin to the surface of the molten alloy. The practical effect of this is to make the alloy appear colder and less fluid than is really the case. Careful observation readily overcomes this difficulty.

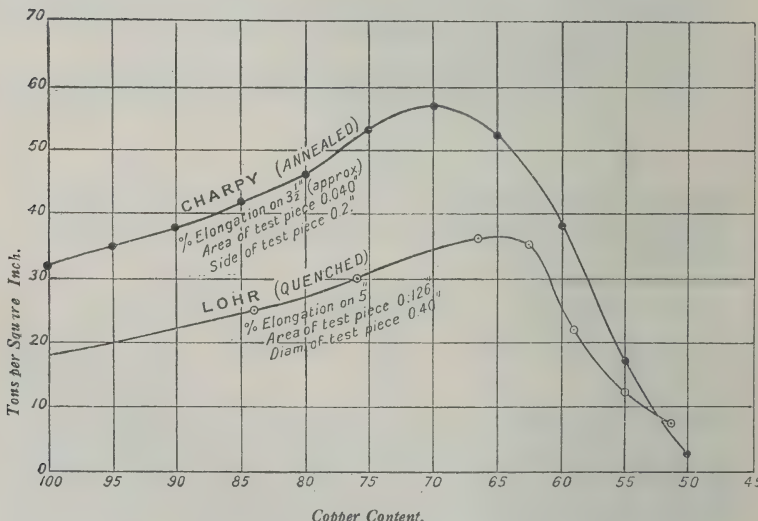
There is little doubt that the pyrometer is, in the hands of careful workers, the best means of determining the temperatures of metal or alloy in the ladle or crucible.

(See also Zinc-Tin Alloys, page 2740.)



Copper Content.

FIG. 13.



Copper Content.

FIG. 14.

Cast Brass.

Cast brass is somewhat variable in composition, but usually contains about 66 per cent. of copper, this percentage being that found in English standard brass.

The metals employed in the production of cast brass are not generally selected with such care as are those used in the manufacture of malleable brass. Lead, tin and iron are common impurities.

Lead in proportions varying from 1 to 3 per cent. is frequently added for the purpose of facilitating machining. It reduces the tenacity and hardness and increases the corrodibility of the resulting alloy, and is liable to segregate in those parts of the castings that solidify latest on cooling.

Tin tends to harden brass and is added in quantities up to 3 per cent., though 2 per cent. is not generally exceeded.

Iron hardens and increases the tenacity of brass.

The presence of more than one of these elements in quantity is to be deprecated, as their combined effects on the mechanical properties of the resulting alloy are likely to be injurious.

The mechanical properties of cast brass of average composition (66 per cent. of copper) and containing only small quantities of impurities or added elements are :—

Yield point, 6 tons per sq. in.; Tenacity, 14 tons per sq. in.; Elongation, 40 per cent.

A number of alloys, adapted for particular purposes, are tabulated below :—

Alloy.	Cu. Per cent.	Zn. Per cent.	Other Metals. Per cent.
Very delicate castings	86·00	14·00	—
Good yellow brass	75·00	25·00	Sn. 2·00
Name plates	86·00	9·00	Sn. 3·00; Pb. 2·00
Small castings (red)	90·00	10·00	,, ,,
Taps, cocks, etc.	78·00	14·00	Sn. 3·00; Pb. 3·00
Fine castings (yellow)	71·00	24·00	Sn. 2·00; Pb. 3·00
Hydraulic pumps	58·00	38·00	Sn. 2·00; Fe. 2·00

Ductile Brass.

The brasses containing upwards of 63 per cent. of copper are ductile and malleable at ordinary temperatures, provided that the metals used in the production of the alloys be of the best quality, and that the alloys be well annealed during working. The most suitable annealing temperatures for ductile brass are between 650° C. and 700° C.

Lead is admissible in alloys that are to be rolled into sheet, but is injurious in alloys that are to be drawn into wire. It should not be present in such quantity as is liable to create trouble at the annealing furnace.

The most ductile of the brasses contains 70 per cent. of copper and possesses the following mechanical properties when fully annealed subsequent to rolling :—

Yield point . 10 tons per sq. in.; Elongation . 60 per cent. on 2 ins.;
Maximum stress . 23 ,, ; Hardness (Brinell) 120.

Hot-forgeable Brass.

The alloys of copper and zinc containing from 59 to 61 per cent. of copper are characterised by their ability to withstand hot rolling at temperatures ranging from 500° C. to 800° C. They are employed in sheet form for the sheathing of wooden ships and in bar form for the manufacture of bolts, fastenings, etc. They are forgeable under the drop hammer and, hence, are frequently used in the manufacture of stampings. In this last connection it is particularly noteworthy that constancy of composition must be attained, on account of the large variations in machining properties accounted for by small changes in the copper content. The alloys in the range 57 to 63 per cent. of copper are forgeable, though not capable of withstanding rolling, in the temperature range already stated, and may be considered here.

All the above alloys are retained in a harder, stronger, and less ductile condition if quenched from temperatures between 750° C. and 800° C. than if allowed to cool slowly. They are liable to spontaneous cracking if worked at temperatures below 600° C., which liability, if thought to be inherent, can be lessened if the alloys are annealed at temperatures between 200° C. and 300° C., subsequent to working. The best temperatures for annealing, with a view to reducing variations in the mechanical properties due to variations in the mechanical and thermal treatment, are below rather than above 650° C. The temperature range (750° C.–800° C.) is, according to Stead, a dangerous one in which to conduct the annealing of hot-forgeable brass.

The average mechanical properties of fully annealed cast 60/40 brass are as follows :—

Yield point . 10 tons per sq. in.; Elongation . 35 per cent.;
Maximum stress . 25 ,, ; Hardness (Brinell) . 85.

Drawn rod of 60/40 composition is obtainable having the following average mechanical properties :—

Yield point	. 28 tons per sq. in.;	Elongation .	. 20–30 per cent. on 2 ins.;
Maximum stress	. 32 ,, ;	Hardness (Brinell)	140.

The last factor appears to be dependent on the diameter of the rod in question, being least when the diameter of the rod is greatest. On account of the almost infinite variety of hot- and cold-working possible in the treatment of these alloys almost infinite variations in mechanical properties are obtainable.

Effect of certain Metals on Brass.

Tin raises the tenacity, increases the hardness and resistance to corrosion and lessens the elongation of the 60/40 alloy, to which it is added commercially to make Naval brass. The latter contains 60–62 per cent. copper, 1–1½ per cent. tin, and the rest zinc. Not more than 2 per cent. of tin should ever be present ; 4 per cent. induces great brittleness.

Iron increases the tenacity and hardness of brass. The difficulty of dissolving iron in brass was first overcome by a special process, the invention of Dick, whose alloy, generally containing 55–57 per cent. copper, 42 per cent. zinc, 1–2 per cent. of iron and traces of phosphorus, is well known.

Iron is now generally added to brass in the form of ferromanganese, an alloy of iron and manganese which is readily dissolved in molten brass.

Manganese is added to brass with a view to improve the mechanical properties of the same. The resulting alloys are divisible into two classes :

(*a*) Alloys in which either no manganese or traces only of manganese are present, *i.e.* alloys to which the element has been added for purposes of deoxidation.

(*b*) Alloys in which appreciable quantities of manganese are retained in solution. These may be subdivided into (i) such as are suitable for rolling into rod and containing up to 0·05 per cent. of manganese, and (ii) such as are suitable for casting and containing less than 60 per cent. of copper, and up to 2·0 per cent. of manganese.

The manganese is introduced into the alloys by the addition of ferromanganese or cupro-manganese.

These alloys are forgeable when heated to temperatures above 750° C. They resist the corrosive action of sea water, and are employed in the manufacture of ships' propellers. Iron, aluminium and tin are generally present in manganese ' bronze.'

' Delta ' Brand Alloys.

The metals and alloys sold by the Delta Metal Co., Ltd. (of London and Birmingham), under their registered trade-mark ' Delta,' are employed for a very great variety of purposes, the composition varying widely according to the requirements and purposes for which each of these metals or alloys is more particularly adapted. Some of them are based upon the introduction and chemical combination of definite quantities of iron and other elements in copper-zinc alloys. The effect of iron on brass has already been noted ; the difficulty of introducing it in definite quantities was first overcome by the late Mr. Alexander Dick, the founder of the Delta Metal Co., Ltd., who adopted the name ' Delta ' (the Greek equivalent of the initial letter of his name) as a trade-mark. In most of the alloys which may be classed under the ' Brasses,' the copper content lies between 57 and 62 per cent., that of zinc between 42 and 38 per cent., whilst some contain iron, phosphorus, manganese, or other metals, up to a total of about 2 per cent.

The following alloys, designated by the trade name ' Delta,' and manufactured by the Delta Metal Co. Ltd., find wide application.

Delta Bronze Nos. I and IV are practically incorrodible, and consequently of very great durability, even when used in strongly corrosive mine-waters, etc. ; they are not attacked by sea-water, and resist acids much better than other copper alloys. On account of their great strength and resistance to corrosion, these alloys are largely used for parts of marine engines and mining and hydraulic plant which require a strength not less than that of the best steel, but at the same time freedom from corrosion—such as pump rods, piston rods, shafts, cranks, plungers, spindles, rams, etc. For propellers and propeller blades, Delta bronze is in great demand, and it is also successfully used for parts of ordnance, etc.

These alloys are malleable bronzes of very great strength, exceeding, even in the cast state, the strength of mild steel. They can be cast with facility, and will produce perfectly sound and homogeneous castings. When heated to a dull red heat, they become soft and highly malleable, and can then be readily forged, stamped, rolled, or pressed, to any extent required. These operations increase the strength considerably, as will be seen by the following copies of tests.

Description of Metal.	Diameter. In.	Area. Sq. in.	Ultimate Strength. Tons per sq. in.	Elongation in 2 ins. Per cent.	Reduction of Area. Per cent.
		Delta Bronze, No. I.			
Cast . . .	0·500	0·1963	41·30	20·0	20·4
Extruded bars .	0·502	0·1979	49·82	26·0	24·9
		Delta Bronze, No. IV.			
Cast . . .	0·611	0·293	23·89	21·0	20·1
Extruded bar .	0·500	0·1963	37·1	27·0	20·0

Extrusion Process.

The process of extruding copper and its alloys, the invention of the late Mr. Alexander Dick, developed and worked by the Delta Metal Co., Ltd., of London and Birmingham, under numerous subsequent new patents and improvements, consists of the pressing or squeezing of heated metals through dies of any desired cross-section, by hydraulic pressure varying according to the section to be produced and the character of the metal operated upon.

Dick's extruded bars have a perfectly smooth and uniform surface, free from cracks or other defects; size and shape are of the greatest accuracy, and owing to their superior finish, machining is reduced to a minimum. The Company are able to produce extruded rods as ordinary round or pinion wire weighing a fraction of a pound per foot per run, to heavy round, square or hexagon rods, or other sections, more or less complicated, weighing as much as half a cwt. and over per foot. The facility of manipulation ensures rapid output, so that sections not regularly kept in stock can be supplied at very short notice.

The Delta Metal Co., Ltd., are not only the original, but claim to be also the largest manufacturers of extruded rods and sections. They supply these in various metals and alloys: in 'Delta' bronzes Nos. I, II, IV, and VII, Heagard bronze, manganese and aluminium bronze, brass, yellow metal, naval brass, etc.

They make a speciality of high-speed turning and screwing brass ('Delta' Brand and 'Dixtrudo' Brand) in every variety of shapes and sections. This material, like the stampings and pressings in brass, bronze, and copper made by the Delta Metal Co., Ltd., is used largely for repetition work and mass production, and supersedes castings.

BULL'S METALS.

(Bull's Metal & Melloid Co. Ltd., Glasgow.)

Bull's Metals are strong, malleable alloys of good casting qualities, and equal to good gunmetal in resistance to corrosion. They are manufactured in two qualities, No. II and No. III.

Alloy No. II is suitable for founding purposes, and extensively used for propellers and propeller blades, parts of guns and gun carriages, requiring the strength of cast steel with great toughness and resistance to corrosion.

Alloy No. III is very malleable and can be rolled, forged, stamped, or otherwise wrought at a red heat; this metal also casts well. Its composition ensures great resistance to corrosion and wear. It is absolutely non-magnetic.

Rolled in round, hexagon, angle, and section bars, or into sheets and plates; forged or stamped Bull's metal is used for pump rods, centrifugal pump spindles, rams, stern shafts, sluice valve spindles, parts of marine and hydraulic machinery generally. Forged propeller blades, propeller studs and nuts. Bolts, nuts, screws, studs, and nails. Parts of torpedoes and torpedo boats, ordnance, ammunition, etc. Condenser plates, strainer plates, doctor blades. Hull plates and angles for launches, torpedo boats, yachts, sailing and rowing boats.

The elastic and ultimate resistance to tensile, crushing, and torsional stresses are greater in the case of wrought Bull's metal than in mild steel, and higher working strains may therefore be used with Bull's metal. Where resistance to the action of water or chemicals enters as an important factor, Bull's metal, whether wrought or cast, becomes specially superior to steel.

TENSILE TESTS OF BULL'S METALS.

Dimensions.	Area. Square inch.	Reduction area at fracture.	Extension.	Ultimate Stress.	Remarks.
Diam. Inch.		Per cent.	Per cent.	Tons per sq. in.

0·690	0·3739	37·8	20·0 ,,	25·01	Rolled, medium finish.
0·688	0·3717	30·6	29·0 on 6 ins.	31·47	Cast medium.
0·750	0·4418	24·2	22·0 on 3 ins.	38·68	Cast hard.

'MELLOID.'

(Registered Trade Mark.)

This alloy is a malleable genuine bronze containing no inferior metal; its resistance to corrosion is very great. Its tensile strength in a rolled state when suitably finished is as high as that of mild steel; the strength is not appreciably affected at the temperature of high-pressure steam, whilst copper at such heat is very much reduced in strength and elasticity.

The alloy is perfectly malleable at *all* temperatures, from cold to blood-red heat; it has no brittle stage at a black heat like most metals and alloys, and at a red heat it is much superior in strength and toughness to mild steel under such conditions, and the alloy, under all conditions, is exceedingly tough.

'Melloid' meets the mechanical requirements referring to copper, naval brass, and rolled bronze specified by the Admiralty, the principal railway companies, and consulting engineers.

It is claimed that 'Melloid' will be found superior to all brass alloys, including naval brass, yellow or Muntz metal, and also to wrought copper, wherever a combination of toughness, great strength, and a maximum resistance of corrosion is required.

NICKEL ALLOYS.

Ferro-Nickel Alloys.

These alloys generally contain 25–30 per cent. nickel, 0·3–0·5 per cent. carbon. They are austenitic, and not subject to heat-treatment. They are tough and strong, while some have a low thermal expansivity and are very resistant to corrosion in air, fresh and sea water. They may be forged or rolled, but not so readily as ordinary steel.

Average tensile properties in the normal condition (not heat-treated):—

	25–28 per cent. Nickel.	30–35 per cent. Nickel.	35–38 per cent. Nickel.
Tensile strength, tons per sq. in.	38–41	38–42	45–51
Yield point, tons per sq. in.	15·5–22	18–22	28–35
Elongation on 2 in. per cent.	30–35	30–40	25–35
Reduction of area, per cent.	50–60	40–60	50

Alloys containing about 25 per cent. nickel are used for electrical resistance wire in the construction of rheostats and electrical heaters. Within the range of composition from 20–30 per cent. nickel, the ferro-nickel alloys may be readily obtained in a non-magnetic condition by cooling at normal rates from rolling or forging temperatures.

Permalloy.—A nickel-iron alloy, nickel 78·5 per cent., iron 21·5 per cent., with impurities as low as possible. Heat-treatment. Heat to 200° C. for 1 hour, cool slowly, reheat to 600°C. cool at a definite rate in air. This alloy possesses high magnetic properties, the maximum permeability is largely in excess of the highest values found for silicon steels. The presence of impurities affects the permeability and carbon is especially harmful, but the effect of changes in the heat-treatment are much greater than those due to small quantities of impurities.

Typical composition of Permalloy: nickel, 78·23; iron, 21·35; carbon, 0·04; silicon, 0·03; manganese, 0·22; sulphur, 0·035; phosphorus, trace; cobalt, 0·37; copper, 0·10.

μH values for Permalloy, 50 per cent. nickel alloy, 4 per cent. silicon-iron alloy, and pure iron.

Magnetising Force H. Gilberts per cm.	Permeability $\mu = \frac{B}{H}$			
	Permalloy.	50 % Ni.	4 % Si–Fe.	Pure Iron.
0·05	74,000	69,000	5,000	2,400
0·1	50,000	60,000	7,000	3,600
0·2	30,000	39,000	13,000	10,000
0·4	18,000	23,000	15,500	26,500
0·6	13,000	16,500	14,500	21,500
0·8	10,000	13,000	11,000	16,500
1·0	8,000	10,000	10,000	14,000

Mumetal.—A nickel-iron alloy containing copper and manganese. Its initial permeability somewhat less than that of the binary alloy, but has a higher electrical resistivity which is of value in keeping down eddy-current losses.

The advantage of the nickel-iron alloys are pronounced in very low magnetic fields and are particularly well marked in respect of 'initial permeability'—*i.e.* the permeability in fields whose

strength approaches zero. Ternary nickel iron alloys containing such elements as aluminium, cadmium, chromium, cobolt, copper, magnesium, molybdenum, tantalum, titanium, tungsten, vanadium, etc., have been developed to meet special requirements.

In general, the alloys must be made from as pure metals as possible, the presence in the alloy of certain impurities, such as sulphur and carbon, being very detrimental. Heat-treatment is of great importance, also care must be taken to protect metal from stress or work after treatment. An alloy with 81 per cent. nickel is less sensitive in this direction, and the addition of molybdenum also helps.

Permax.—Nickel-iron alloy containing added elements. It does not possess the high permeability of some of the other alloys, but is remarkably constant in certain of its magnetic properties —*e.g.* under fields varying from 200 gauss to 1 gauss, the coercive force changes only from 0·48 to 0·45.

Invar.—See p. 2703.

Elinvar.—An alloy of 36 per cent. nickel and about 12 per cent. chromium (or its equivalent where small quantities of manganese, tungsten, or carbon are used in conjunction with the chromium additions).

At ordinary temperatures has a practically invariable elastic modulus coupled with a very low thermal expansivity.

Dilver.—Forty per cent. nickel, has a coefficient of thermal expansion approximately that of ordinary glass.

Platinite.—Forty-six per cent. nickel, has a coefficient of thermal expansion equal to that of platinum.

A.M.F. Alloy.—Fifty-seven per cent. nickel, has the same thermal expansion as steel but more stable and less liable to corrosion.

Nickel Silver.

The most harmful impurities are lead (except in rods or castings intended for machining, in which case lead up to 3 per cent. is purposely added to improve the machining quality of the alloy), sulphur, and carbon, and precautions should be taken that these elements are kept within very narrow limits. Tin, iron, and unreduced oxides may also be present as impurities.

Melting operations are carried out usually in coke-fired pit type crucible furnaces. Electric furnaces are also used, and the metal is cast into iron moulds in forms suitable for rolling sheets or rods. The rolling and drawing of nickel silver is carried out at normal temperatures, since none of the ordinary commercial alloys are capable of being hot-worked.

Annealing temperature: Nickel, less than 14 per cent., 600–650° C.
Nickel, 16 per cent. and upwards, 700–750° C.

Average mechanical properties (nickel 18 per cent. and up) cold-worked (rolled or drawn) and fully annealed. Yield stress, 15 tons per sq. in. Ultimate stress, 26–30 tons per sq. in. Elongation on 2 ins., 35–40 per cent. Reduction of area, 45–50 per cent. With nickel less than 18 per cent.: Yield stress, 12–14 tons per sq. in. Ultimate stress, 23–26 tons per sq. in. Elongation on 2 ins., 50–55 per cent. Reduction of area, 50–55 per cent.

The mechanical properties of nickel silver are not as important as other physical properties —*i.e.* whiteness of colour and brilliance of polished surface, resistance to corrosion.

The alloy possessing the finest silvery whiteness is that produced from a specification of approximately equivalent weights of nickel, copper, and zinc. This composition is only suitable for castings. It is not so important commercially as the alloy coming next to it known as B.B. and containing 30 per cent. nickel. In general, the colour varies directly with the nickel content, those alloys of highest nickel content giving the whitest colour and most lustrous polish.

Results of research show that the tendency of commercial nickel silver to 'burn' is increased (*a*) by increasing the nickel content, (*b*) as the ratio of the zinc to the copper is increased, and (*c*) with the amount of impurities present.

The following alloy is stated to be possessed of the best all-round properties:—

Copper, 46 per cent.; Nickel, 39 per cent.; Zinc, 20 per cent.

Platnam.

Consists of 54 per cent. nickel, 33 per cent. copper, and 13 per cent. tin. It is used for the manufacture of valve seats and valves which have to withstand the action of superheated steam.

Nickel Chromium.

These alloys have a composition which varies considerably according to the purpose for which they are required, but in those of commercial utility the nickel content lies within the limits of 60 per cent. and 80 per cent. and the chromium content beetwen 12 per cent. and 22 per cent.

The balance consists mainly of iron, with small percentages of manganese, silicon, aluminium, and carbon, other elements being present only as traces of impurity.

A typical alloy has the approximate composition of nickel 66 per cent., chromium 20 per cent., iron 10 per cent., the balance consisting of the above-mentioned minor components.

Physical Properties.

Tensile strength in cast state . . .	25 to 30 tons per sq. in.
Melting-point	1300° to 1350° C.
Density	·29 lbs. per cu. in.
Specific heat	·11

These alloys have two outstanding properties which have great commercial value, namely: their strength is well maintained at high temperatures, and they are chemically inactive under a wide range of conditions even at high temperatures. Thus they resist the attack of furnace gases to a marked degree, and unless sulphur is present in unusually large quantities, their life at temperatures up to 1200° C. is very considerable.

The actual life of articles made of this alloy is greatly dependent upon conditions, but a period approaching 10,000 hours at such temperatures is by no means unusual.

The above properties make the alloys eminently suitable for the manufacture of such articles as pyrometer sheaths, case-hardening boxes, furnace parts, retorts, muffles, in which rôles they have been of great assistance to engineers in overcoming difficulties due to the severe conditions of temperature and corrosion which modern works practice produces.

Such alloys have long been recognised, when drawn into wire or rolled in strip form, to be extremely valuable for such electrical purposes as windings for electric furnaces and stoves.

The alloys are frequently of service to chemical engineers for use with corrosive fluids at normal temperatures, and have found application in the manufacture of such articles as acid pumps and valves subject to attack by acids and acid vapours.

An alloy designated the 'Emperor' chrome nickel alloy is manufactured by Messrs. Sutcliffe, Speakman & Co., Ltd. and is of great durability.

A large number of pyrometer tubes, case-hardening boxes, and similar utensils made of the alloy are in use in some of the principal works of the country.

Heat- and Acid-Resisting Alloys.

The following table gives the analysis of some typical commercial alloys:—

Alloy No.	C.	Mn.	Si.	Cr.	Ni.	Co.	Al.	Cu.	W.	Mo.	Fe.
1	0·94	1·1	1·9	21·0	68·0	—	—	—	—	—	7·0
2	0·27	0·06	3·92	29·1	62·4	—	—	—	—	—	4·9
3	0·09	0·02	0·46	15·6	81·2	1·56	0·42	—	—	—	0·8
4	0·50	0·79	0·80	13·68	5·75	—	—	—	—	—	27·3
5	—	0·98	1·04	21·07	60·7	—	1·09	6·42	2·13	4·7	0·76
6	1·13	2·2	0·63	15·5	64·9	—	—	—	—	—	15·8
7	1·37	1·90	0·49	8·5	40·0	—	—	5·5	—	—	42·0
8	0·60	1·88	1·17	13·2	59·9	—	—	—	—	—	23·2

Alloy No. 1 has the most general useful analysis. Silicon rather higher than necessary. Narrow freezing range solidification complete about 1325° C.

No. 3 alloy is suitable for the manufacture of wire, but is expensive. The cobalt probably due to impurity in the nickel. Melting range, 1230–1390° C.

No. 4 alloy is rather poor, suitable for resistance wire.

No. 5 alloy, generally known as Parr's Alloy, developed specially for the manufacture of Mahler bombs.

No. 6 alloy is an average alloy. The carbon is high, showing that a low-grade ferro-chrome was used, and the manganese is also unnecessarily high.

No. 8 alloy is a poor type of alloy. Iron far too high and nickel very low. The copper should not be added to an alloy intended for general purposes; it is useless in a heat-resisting alloy.

Maximim tensile strength of alloy No. 1 in cast state, 25–30 tons per sq. in.; alloy No. 4 in rolled sheets; yield stress, 28 tons per sq. in.; ultimate strength, 50 tons per sq. in. Elongation, 8 per cent. Reduction of area, 12 per cent.

Practically all the alloys are capable of being softened and rendered more ductile by heat-treatment, and in that respect behave as most non-ferrous alloys—*i.e.* they become more ductile when quenched. (*Kayser.*)

Acid-Resisting Alloys.

The corrosion-resisting properties vary according to their composition, but if the silicon alone does not exceed 2 per cent., and the combined carbon, silicon, and manganese 4 per cent., the properties of these alloys are very similar. Nickel-chromium alloys offer a perfect resistance to the corrosive action of the atmosphere in the presence of either hard or soft water, or sea-water. In the case of stainless steel it is necessary that it be correctly heat-treated and free from surface scale or pit marks.

No heat-treatment is necessary for nickel-chromium alloys, and it is not necessary even to polish or grind the surface.

ACID-RESISTING ALLOYS.

Reagent.	Temperature. ° C.	Nickel-Chromium Alloys.	Stainless Steel.
Acetic acid, 20 per cent. solution	15–20	No attack visible	Attacked
	100	General etching	Attacked
Citric acid, 30 per cent. solution	15–20	No attack	Marked corrosion in 24 hours
	100	Stained yellow	Marked corrosion in 24 hours
Nitric acid, 1·20	15–20	Etched	Etched
	100	Attacked	—
Sulphurous acid	15–20	Discoloured	Rapid attack
Dry battery mixture	15–20	Slight pitting	Marked corrosion
	100	Pitting	Marked corrosion
Acetic anhydride	15–20	No visible attack	Badly pitted in 5 hrs.
	100	No visible attack	Badly pitted in 5 hrs.
Sulphuric acid, 50 per cent. solution	15–20	General attack	Rapid attack
	100	Badly corroded	Rapid attack
Phosphoric acid, 75 per cent. solution	15–20	No visible attack	Attacked
	100	Stained	General attack
Ammonium sulphate, 50 per cent. solution	15–20	No attack	General attack
	100	Brown stain	General attack

(*Kayser.*)

Platinite.

Platinite is an alloy of iron, nickel, and carbon, which is used extensively for scientific instruments for standard measurements of length because of its peculiar quality of being practically non-expansive when heated to high temperatures. It is also used in incandescent electric lamps where the wire connections fused into the glass must have so small a coefficient of expansion as not to cause fracture in the glass. This alloy contains about 46 per cent. of nickel and 54 per cent. of iron, with a very small percentage (0·15 per cent.) of carbon.

Monel Metal.

(C. & J. Weir, Ltd., Cathcart, Glasgow.)

This is a natural nickel alloy, and which, after refining, has an average composition of nickel 67 per cent., copper 28 per cent., iron 3 per cent., manganese 2 per cent.; a small percentage of carbon may also be present. In appearance it is very similar to pure nickel and takes the same high finish, but has a slightly softer and somewhat more silvery lustre. It is as strong, tough, and ductile as steel, and under corroding influences far superior to copper, gun-metal, and bronze. It machines readily, and can be rolled, drawn, cast, forged, soldered, brazed, and welded.

Average tensile properties: Hot-rolled metal, 30–42 tons per sq. in., according to size and treatment. Ordinary cast metal, 19–25 tons per sq. in., according to character of casting.

Monel metal resists sea-water, alkalies, and some dilute acids, but is not suitable where nitric acid is present. One of the most valuable properties is its tensile strength at elevated temperatures. For example, at a temperature of 400° C., a forged rod has a tensile strength of over 35 tons (see page 2705).

Average Physical Properties.

Melting point, 1360° C.
Pouring temperature of castings, 1500° C.
Forging temperature, 1040–1100° C.
Annealing temperature, 700–900° C.
Specific gravity, 8·82.
Weight per cub. in. = ·323 lbs.
Shrinkage allowance for castings, $\frac{1}{4}$ in. per foot.
Coefficient of expansion, 0·0000137 per ° C.
Electrical resistivity, 48 michroms per cm.^{3}
Electrical conductivity, 3·4–5 per cent. of copper.
Heat conductivity, $\frac{1}{15}$th that of copper.
Brinell: Cast metal, 120–140.
Hot-rolled sheets and rods, 150–190.
Cold-drawn bar, 200–217.

Monel metal in the rolled condition is magnetic at ordinary temperatures, but becomes non-magnetic when heated from 100–150° C. The magnetic change is reversible, the metal becoming magnetic on cooling. Hysteresis tests show that under a magnetising force (H) of 100 C.G.S. units the number of lines per cm.^{2} (B) is 2,460. The remanence is found to be 990, and the coercive force 1·1.

Casting.—Melting practice, also gates and risers similar to that used for steel. The care required for moulding and ramming more nearly resembles that for non-ferrous metals. Core must be collapsible to allow free shrinkage of the metal.

Metal can be melted in graphite crucibles, using (*a*) oil-fired pit furnaces; (*b*) oil-fired clay brick-lined reverberatory furnaces; or (*c*) in clay brick-lined or basic-lined electric arc furnaces. All ladles and crucibles used for transferring the metal should be preheated to conserve the heat in the metal.

Forging.—Practice similar to that for steel. The metal is harder under the hammer than mild steel and approaches closer to the nickel steels in behaviour. Oxide scale formed is strongly adherent and will not free itself even under hammer blows with steam and salt. Metal becomes hot-short just above maximum forging temperature.

Annealing should be carried out in a reducing atmosphere. General practice is to anneal in a cast-iron box covered with fine charcoal and a cover sealed with fireclay.

ALUMINIUM.

Aluminium Brass.

Aluminium acts as a deoxidiser and is added to cast and hot-forgeable brass, for the purpose of improving their mechanical properties, in quantities varying from 0·3 to 1·5 per cent.

Typical tests of cast aluminium brass, containing 38 per cent. of zinc, 2 per cent. of aluminium, and 2 per cent. of lead, are :—

Yield point	18 tons per sq. in.
Maximum stress	34 ,,
Elongation	12 per cent.

Melting Points of Commercial Brasses.

(*Gillett & Norton.*)

	Copper.	Zinc. (as desired).	Tin.	Lead.	Copper.	Zinc. (by analysis).	Tin.	Lead.	No. of Tests.	Melting Point.
Red brass	85	5	5	5	—	—	—	—	8	970°C.
Low-grade red brass	82	10	3	5	81·5	10·4	3·1	5·0	4	980°C.
Half yellow, half red	75	20	2	3	75·0	20·0	2·0	3·0	3	920°C.

Manganese brass	Copper 56, Zinc 41, Iron 1·5, Tin 0·9 per cent. Aluminium 0·45, Manganese 0·15 per cent.								6	870°C.

COPPER AND TIN ALLOYS.

Gun-metal.

The alloys of copper and tin containing upwards of 86 per cent. of copper are possessed of high tenacity and elasticity. Those containing from 89 to 91 per cent. of copper are the most important and are known as 'gun-metals.'

The addition of tin to these bronzes results in an increase in the hardness of the resulting alloy. Gun-metal is rarely manufactured from specially selected metals and frequently contains lead, zinc, etc. The Admiralty specification for gun-metal is as follows :

Copper	88 per cent.
Tin	10 ,,
Zinc	2 ,,

the specified tests for this material being

Maximum stress	14 tons per sq. in.
Elongation	7½ per cent.

Gun-metal containing 90 per cent. of copper and 10 per cent. of tin should give the following tests :—

Yield point	7 tons per sq. in.
Maximum stress	15 ,,
Elongation	15 per cent. on 2 ins.

Bell-metal.

The alloys of copper and tin containing from 75 to 86 per cent. of copper are used in the manufacture of bells ; iron, zinc and lead are frequently added to the alloys either for cheapness or variety of tone.

Effect of Certain Elements on Bronze.

ZINC.

Gun-metal, Bearing Metal, etc.

The alloys of copper, tin and zinc are rarely, if ever, free from elements such as lead, iron, etc. These alloys may be divided into two classes :—

(i) Alloys containing from 7 to 12 per cent. of tin, up to 6 per cent. of zinc, and up to 2·5 per cent. of lead. These alloys, among which may be noted gun-metal to the Admiralty specification, are used in the manufacture of castings, such as cocks, stuffing-boxes and pump barrels, and for bearings which are subject to but little friction.

(ii) Alloys containing from 12 to 20 per cent. of tin, up to 5 per cent., though rarely more than 2·5 per cent., of zinc and up to 5 per cent. of lead. These alloys are used in the manufacture of heavy bearings, e.g. railway wagon and locomotive axle boxes. The majority of alloys of this class contain from 14 to 16 per cent. of tin and from 1·5 to 2·5 per cent. of zinc.

Zinc combines with the oxides and free oxygen of the bronzes, producing greater fluidity in the molten state, and hence freedom from ' pinholes ' in the solid state.

LEAD.

Bearing Metal, etc.

The best bronzes should contain not more than 0·15 per cent. of lead, on account of its deleterious effect on the mechanical properties of these alloys generally.

Bearing metals having a bronze matrix and containing up to 40 per cent. of lead are in common use. A usual composition for bearings of this type is :—

Copper	64 per cent.
Lead	30 ,,
Tin	5 ,,
Nickel	1 ,,

The nickel is added to prevent the liquation of the lead. It increases the rate of cooling of the alloy and thus assists in the retention of the lead in the finely divided form.

Lead does not alloy with bronze, but separates out of the molten mass, as the same cools, in the form of globules. The lead bronzes may, therefore, be considered to consist of a network of bronze whose meshes enclose the lead content of the alloys in question.

PHOSPHORUS.

Phosphor Bronze.

Phosphorus acts as a deoxidiser and is added in small quantities for the purpose of deoxidation to copper. Not more than 0·15 per cent. is allowable.

The term ' phosphor bronze ' is applied to the alloys grouped below.

(i) Bronzes to which phosphorus has been added as a deoxidiser and containing either no phosphorus or merely traces of the element.

(ii) Bronzes containing less than 9 per cent. of tin and up to 0·25 per cent. of phosphorus. These alloys are forgeable and are relatively non-corrodible. They are employed for rolling and drawing into wire and rod, and in the manufacture of general castings; in the latter case lead is occasionally added in quantities up to 5 per cent. The forgeable alloys of this group generally contain less than 5 per cent. of tin.

(iii) Bronzes containing from 8 to 14 per cent. of tin and from 0·25 per cent. to 1·00 per cent. of phosphorus. These alloys are employed for casting purposes in the manufacture of machine parts likely to be exposed to great friction. Lead up to 5 per cent. is added in certain cases.

Phosphorus is added to these alloys in the form of phosphor copper or phosphor tin.

The tensile strength of phosphor bronze varies from 14 to 18 tons per square inch, and the elongation from 6 to 10 per cent.

'Delta' Brand Alloys.

(The Delta Metal Co. Ltd.)

Delta Bronze No. V. is an improved bearing metal of great strength and durability, and comparatively low price. It is particularly suitable for reducing friction at heavy pressures and high speeds, and is used for worm wheels for large cranes and other heavy machinery, hot neck rolls, locomotive slide valves, axle box, coupling, and connecting rod bushes, railway and carriage bearings, bushes, sliding surfaces, and other parts of machinery subject to heavy frictional wear. The metal is easy to tool, and requires no special precautions in casting.

Another metal used in lieu of phosphor bronze or gun-metal is 'Delta' Bronze No. VI., which produces fine, close-grained castings of great strength.

Melting Points of Commercial Bronzes.

(Gillett & Norton.)

	Copper.	Tin. (as desired).	Lead.	Zinc.	Copper.	Tin. (by analysis).	Lead.	Zinc.	No. of Tests.	Melting Point.
Gun-metal	88	10	—	2	—	—	—	—	4	995°C.
Leaded gun-metal	85·5	9·5	3	2	85·4	9·7	3·0	1·9	6	980°C.
Leaded bronze	80	10	10	—	—	—	—	—	3	945°C.
Bronze with zinc	85	10	—	5	84·6	19·4	—	5·0	4	980°C.

COPPER AND ALUMINIUM ALLOYS.

Aluminium Bronze.

The alloys known as the 'aluminium bronzes' are solid solutions of copper and aluminium containing not less than 88 per cent. of copper. Of these alloys that containing 10 per cent. of aluminium is the strongest, though the alloys containing less than this percentage are of industrial importance. These 'bronzes' are of use, firstly, on account of their valuable mechanical properties and, secondly, on account of their resistance to corrosion. They are malleable both when hot and when cold; the alloys containing between 8 and 12 per cent. of aluminium are affected in a marked degree by heat-treatment.

Following are tabulated the mechanical properties of some of these alloys :—

Percentage of Aluminium.	Yield Point. Tons sq. in.	Max. Stress. Tons sq. in.	Elongation. Per cent. on 4 in.	Remarks.
2·5	—	20·0	40·0	Cast.
5·0		25·0	55·0	Cast.
10·0	18·0	35·0	25·0	Cast in chill.
10·0	18·0	46·0	25·0	Cast rod reduced 25 per cent. by forging hot. Annealed.
10·0	15·0	40·0	30·0	Rolled bar.
10·0	40·0	50·0	3 0	Rolled bar quenched at 900° C.

The following are tests of the 'R3' and 'R4' aluminium bronzes, manufactured by the British Aluminium Company :—

R3 Bronze.—Average breaking load, 34·04 tons; average elongation, 21 per cent.; maximum breaking load, 37·6 tons; maximum elongation, 35 per cent.; minimum breaking load, 32·8 tons; minimum elongation, 12·5 per cent.

R4 Bronze.—Average breaking load, 41·8 tons; average elongation, 9·75 per cent.; maximum breaking load, 43·7 tons; maximum elongation, 13 per cent.; minimum breaking load, 39·8 tons; minimum elongation, 6·5 per cent.

COPPER AND MANGANESE ALLOYS.

Manganese Bronze, Manganin.

The term 'manganese bronze' is applied to copper-zinc alloys of 60/40 composition to which small quantities of manganese have been added. There are, however, alloys of copper and manganese of industrial application which rightly should be admitted under this heading. The alloys of copper and manganese containing up to 5 per cent. of the latter element are harder and tougher than is copper. Those containing from 2 to 4 per cent. of manganese are frequently employed in situations where high temperatures are existent, on account of their retention of their mechanical properties under these conditions.

The following figures represent the results obtainable by stamping certain of these alloys at a red-heat (*circa* 800° C.) :—

Copper.	Manganese.	Maximum Stress.	Elongation. Per cent.
97	3	18·5	32
96	4	21·0	60

Manganin is the name applied to an alloy of copper, manganese, nickel and iron, characterised by low electrical conductivity and almost zero temperature coefficient. It is employed in the construction of electrical resistance coils. The composition is somewhat variable, but the following figures will serve to indicate its approximate analysis :—

Copper . .	80 to 84 per cent.	Nickel	up to 12 per cent.
Manganese . .	4 to 15 ,,	Iron	Difference.

COPPER AND NICKEL ALLOYS.

Cupro-nickel, Constantan, etc.

The alloys of copper and nickel containing upwards of 50 per cent. of copper are of industrial importance. The alloys may be divided into three classes.

(i) Alloys containing up to 5 per cent. of nickel and having the property of resisting high temperatures without undue deterioration. Of these alloys those containing from 2 to 3 per cent. of nickel have been employed in the manufacture of locomotive firebox tubes. Following are the mechanical properties of the 2 per cent. alloy :—

Maximum Stress.	Elongation. Per cent.	Remarks.
45·0	5·0	Hard rolled.
30·0	45·0	Hard rolled and annealed at 650° C.

Those of the 5 per cent. alloy are very similar in character.

(ii) Alloys containing from 15 to 25 per cent. of nickel and valuable on account of their ability to withstand cold working.

For the best results with these alloys only the purest metals should be employed, as small quantities of such elements as iron, silicon and sulphur are detrimental to the malleability and ductility of the resultant alloy. The maximum percentages of impurities allowable in nickel for this high-class work should be 0·050 per cent. of arsenic, 2 per cent. of cobalt, and 1·5 per cent. of other metallic impurities. The metal should be free from all unreduced oxides. Cupro-manganese, 25–50 per cent., is commonly employed as a deoxidiser in the manufacture of these nickel copper alloys, upwards of 0·25 per cent. being added to charges containing 30 per cent. of scrap. Following are the mechanical properties of the 20 per cent. alloy :—

Maximum Stress.	Elongation. Per cent.	Remarks.
40·0	5·0	Hard rolled.
20·0	35·0	Hard rolled and annealed.

The alloy containing 25 per cent. of nickel has been successfully employed in the manufacture of firebox plates.

(iii) Alloys having low electrical conductivities and whose temperature coefficients of electrical conductivity are practically nil. The 40–45 per cent. nickel alloy, known as 'constantan,' can be drawn into wire, and is employed in the construction of resistance coils and base-metal thermo-couples. Another alloy of this type, containing only 25 per cent. of nickel and 0·5 per cent. of iron, is known as 'nickeline.'

Copper and Silicon.

Alloys of copper and silicon are used for electrical purposes and in the manufacture of telephone and telegraph wires. The effect of silicon is to increase the tensile strength, without seriously affecting the conductivity.

	Tensile Strength (as Cast). Tons per sq. in.
Electrolitic copper	10·8
,, ,, + 0·25 per cent. silicon	14·5
,, ,, + 0·53 ,, ,,	15·5
,, ,, + 1·05 ,, ,,	17·4

ALUMINIUM AND ZINC ALLOYS.

The alloys of aluminium and zinc are of importance as light alloys, their specific gravities varying uniformly from 2·7 to 3·3 as their zinc content increases up to 30 per cent., which may be considered the limiting percentage for those alloys of this series that may be termed 'light.' All those alloys containing upwards of 70 per cent. of aluminium are forgeable at temperatures between 300° C. and 400° C.

These alloys do not allow of their use in casting into intricate shapes, but for all plain casting purposes they are quite satisfactory. Under certain conditions these alloys corrode rapidly; the use of high-grade spelter in their manufacture eliminates this defect. The machining properties of these alloys which are, at all times, superior to those of the pure metal, improve as the zinc content increases.

Below are tabulated certain of the results of tests reported by Messrs. Rosenhain and Archbutt to the Alloys Research Committee of the Institution of Mechanical Engineers.

Zinc. Approx. Per cent.	Condition of Alloy.	Yield Point. Tons per sq. in.	Max. Stress. Tons per sq. in.	Elongation. Per cent. on 2 ins.
5	1	2·70	5·20	16·0
	2	2·80	6·60	29·0
	4	4·30	7·48	33·6
11	1	6·40	9·41	8·0
	2	5·00	10·24	16·0
	3	9·42	13·78	33·0 (on 1 in.)
15	1	9·60	11·14	2·0
	2	5·80	11·69	8·5
	3	11·61	17·92	31·0 (on 1 in.)
	4	6·80	16·38	33·0
20	1	10·00	13·07	0·7
	2	7·80	13·87	4·0
	4	17·30	22·64	20·5
25	1	nil	16·26	1·0
	2	9·10	13·50	3·5
	3	20·24	24·03	27·0 (on 1 in.)
	4	25·00	27·09	16·5
30	1	11·70	16·63	1·5
	2	10·30	17·92	3·0

1. Sand-casting.
2. Chill-casting
3. Hot-rolled bars, ¾ in. diam.
4. ditto 1¼ in. diam.

The addition of copper to certain of the aluminium-zinc alloys improves the mechanical properties of the same. The average results of certain tests on chill-castings of the aluminium-zinc-copper series are given below.

Zinc. Per cent.	Copper. Per cent.	Yield Point. Tons sq. in.	Max. Stress. Tons sq. in.	Elongation. Per cent.
19	1	9·5	14·9	5·5
19	2	12·5	16·5	5·7
20	2	10·4	14·0	3·3
20	3	11·5	16·8	4·5
20	4	10·4	15·3	3·8

ALUMINIUM AND COPPER ALLOYS.

Like the zinc alloys, the commercial alloys are not simple binary alloys, but generally contain iron and silicon, and may also contain Mg, Mn, Ni, Zn, etc.

Al.	Cu.	Use.
93–91·5	7–8·5	General castings.
92	8	General castings, tendency to be brittle.
96	4	General castings, less brittle than 92 : 8 alloy; suitable for rolled sheets, sand-cast cooking utensils.
91–89·5	9–10·5	Light alloy pistons } American automobile practice.
89–86·5	11–13·5	Manifolds }
90	10	Die castings. Permanent mould castings.
88	12	
50	50	'Hardness' or rich alloys; not used for constructiona purposes, but used in the foundry for the purpose of introducing copper into aluminium or aluminium into copper.
60	40	

(See 'Aluminium Bronze,' p. 2732.)

THE IRONMONGER

HARDWARE AND METAL TRADES ADVERTISER.

ESTABLISHED 1859.

PUBLISHED WEEKLY

28 ESSEX STREET, STRAND, LONDON, W.C.2

For over seventy years The Ironmonger has been the leading newspaper published in the interests of buyers of hardware, metals and mill furnishings.

Its news service is invariably up-to-date and its information reliable, while its weekly record of current prices of staple commodities gives to its pages a world-wide reputation as a valuable buyers' guide for the purchasing departments of engineers, shipbuilders, collieries, etc. etc.

All this information is obtainable for the cost of a year's subscription, £1, which sum includes a copy of The Ironmonger Diary and Hardware Buyers Guide, published each December.

To anyone interested a specimen copy of The Ironmonger will be sent on application accompanied by trade card.

The specific gravity increases with increase of copper from 2·7–2·85 for sand-cast alloys for 0–8 per cent. copper. The specific gravity of sand-cast alloys is less than that of chill castings, and that of rolled and drawn alloys is approximately equal to chill cast. In sand-cast alloys the strength increases with increase of copper at the expense of the elongation. In the hot-rolled condition the tensile strength increases up to about 6 per cent. copper and then decreases. The physical properties of these alloys are indicated by the following figures :

92–8 alloy. Ultimate strength, 18,000 lbs. per sq. in.; elongation, 1–1·5 per cent.

97–3 alloy (forged). Yield point, 16,000 lbs. per sq. in.; ultimate strength, 24,000 lbs. per sq. in.; elongation, 4 per cent.

96–4 alloy (rolled, annealed). Ultimate strength, 15,000–28,000 lbs. per sq. in.; elongation, 34–16 per cent.

Tensile strength of hot-rolled bars, 21,000–37,000 lbs. per sq. in. (for 1–6 per cent. copper); elongation varies from 30–18 per cent. For cold-drawn bars—tensile strength, 29,000–45,000 lbs. per sq. in. (for 1–4 per cent. copper); elongation, 14·5–6 per cent.

ALUMINIUM AND SILICON ALLOYS.

A striking property of these alloys is their low contraction, due to the silicon expanding on freezing. Yield exceptionally sound sand castings. Iron should be a minimum, as it has a detrimental effect. These alloys may be forged and both hot and cold formed, and, in their raw condition, are very malleable at the higher temperatures. In addition, they may be welded and will resist all ordinary corrosion, being unaffected by atmospheric conditions. The strength is largely dependent on the actual alloy used, but, in general, is somewhat higher than that of cast iron, and somewhat lower than that of brass. Much higher strengths are, of course, possible in the case of 'modified' alloys. A tensile strength as high as 36,000 lbs. per sq. in. is obtainable, together with a high elastic limit.

These alloys appear under trade names of 'Wilmil' in England, 'Alpax' in America and France, and 'Silumin' in Germany.

Method of preparation of these alloys has a great effect upon their properties. (1) Normal alloy, made by simply melting together aluminium and zinc. (2) Modified alloy, made by direct electrolytic reduction or by the addition of an alkali fluoride or with sodium or potassium to the melted normal alloy.

The silicon in (1) appears as relatively large crystals, and in (2) in high dispersion.

For 'normal' castings—composition, 95–90 Al, 5–10 Si.

For 'modified' castings—composition, 90–85 Al, 10–15 Si.

The simple Al–Si alloys are difficult to machine, and Al–Cu–Si alloys have been developed to overcome this.

OTHER ALLOYS OF ALUMINIUM.

Magnalium.

Magnalium is the name applied to a series of alloys having an aluminium-magnesium base, containing from 1·5 to 10·0 per cent. of magnesium and varying proportions of other elements, *e.g.* copper, tin, nickel, lead.

The table below gives the analyses of certain of these alloys, together with the uses to which they are generally put.

Use of Alloy.	Magnesium.	Copper.	Nickel.	Tin.	Lead.
Strong castings . .	1·60	1·76	1·16	nil	nil
General ditto . .	1·60	1·76	nil	traces	traces
Rolling and drawing .	1·58	0·21	nil	3·15	0·72

'Vickers' Duralumin.'

(James Booth & Co. (1915) Ltd.)

'Vickers' Duralumin' is the trade name applied to a series of quaternary alloys of aluminium, copper, manganese and magnesium, containing over 90 per cent. of aluminium and possessed of high tenacity and hardness. The presence of magnesium confers the property of cumulative hardening on certain aluminium alloys—*i.e.* subsequent to suitable thermal treatment the hardness of the alloy increases slowly to a maximum, which is attained after several days.

Following are typical analyses of 'Vickers' Duralumin':—

Copper.	Manganese.	Magnesium.	Silicon.	Iron.	Aluminium.
3·62	0·35	0·87	0·62	0·045	Diff.
3·00	1·00	2·00	—	1·000	Diff.
3·60	0·40	—	0·50	0·600	Diff.

The specific gravity varies between 2·77 and 2·84. The melting point is about 650° C. 'Vickers' Duralumin' can be rolled, forged, and drawn when hot or cold. According to the purpose for which it may be required, the composition can be modified and the treatment so arranged that the material is susceptible to forging, rolling, and drawing, or it may be arranged that the greatest hardness, with corresponding smaller extension, can be produced. The following table gives a summary in which the properties of 'Vickers' Duralumin' vary by such modifications in the composition and treatment.

Description of the Alloy.	Specific Gravity.	Yield Point. Tons per sq. in.	Max. Stress. Tons per sq. in.	Elongation. Per cent.	Contraction.	Brinell Hardness.
H	2·77	12·06	22·25	23	34	98
681d	2·84	16·5	29·20	18	26	125

These values are for soft rolled plates of 7 mm. thickness.

'Vickers' Duralumin' is supplied in sheets, bars, wires, strips, forgings, stampings, various sections and tubes.

BEARING METALS.*

The requisite properties of good bearing metals are hardness, to resist wear; strength, to bear compression; and plasticity, to allow of ready adjustment of the supported body on the bearing.

Two types of bearing metal are known:—

(*a*) Bearing metals in which the hard constituents of the alloy are distributed indiscriminately throughout a soft matrix.

(*b*) Bearing metals of spongy character; the network of the sponge being moderately hard and tough, the meshwork being soft and plastic.

These types can be grouped according to composition as follows:—

(i) Brasses and bronzes containing compounds of copper with tin, phosphorus, etc.

(ii) Bronzes containing appreciable quantities of lead.

(iii) Alloys having a tin base and containing compounds of tin with antimony, copper, etc.

(iv) Alloys having a lead base and containing compounds of tin with antimony, etc.

(v) General alloys possessed of the characteristics required of a bearing metal.

Of the above, types (i) and (ii) have been considered under the heading of 'Brass' and 'Bronze' (*q.v.*), types (iii) and (iv) are known as 'white' metals, while the majority of the alloys of type (v) can be termed 'white metals.' Of types (iii), (iv) and (v) it has been observed that metals whose atomic weight divided by their specific gravity gives a high number are good anti-friction metals, while the reverse is the case for metals which have a low quotient. Hence the use of lead and antimony for bearing alloys. In using white metal for bearings the best practice is to use the bearings wholly of white metal, discarding the cast-iron shells and using up the old bearings with the addition of a further small quantity of the more volatile constituents. White metal must be melted in a clean vessel and at as low a temperature as possible. Dross and scum in the metal tends to rapid heating in service. For the metals to be properly alloyed the high as well as the low melting points of these must be reached, but care must be taken not to overheat the alloy. For a thorough alloying a temperature of about 500° C. (930° F.) and less has been found to be sufficient. The molten metal should be stirred with a stick of pine, and a layer of charcoal always kept on the surface to prevent oxidation. The rate of cooling affects the size of the crystals and also the wearing quality. As a general rule cooling too slowly and pouring too cold produces a coarse crystal formation which is liable to heat quickly in use. In the case of the tin-antimony alloys it has been found that the best size for the tin-antimony compound cubes is 0·25 mm. edge. Pouring too hot on the other hand results in a soft metal. The shell should be heated to a temperature of 100° C. to 150° C. (212° F. to 300° F.) before pouring the metal into it, as this not only prevents blow-holes, but reduces the tendency of the lining shrinking away from the shell. The bearing should not be disturbed while the lining is solidifying, since vibration tends to enlarge the crystals and produce brittleness. The matrix of the lining should be just stiff enough to support the crystals, and the latter should be as numerous as is consistent with these, lying clear of each other and thereby causing brittleness. A Brinell hardness of 23·5 for an alloy with a lead base and 30 for a tin base has been found to give excellent results.

* See also Bearing Pressures, page 961.

ALLOYS HAVING A TIN BASE.

Tin-Antimony Alloys.

These alloys, which are of type (*a*) (p. 2736), are the basis of Britannia metal. The following table indicates the uses of certain of these alloys.

Tin.	Antimony.	Use of Alloy.
86	14	For seats of stop-cocks.
80	20	For plugs of stop-cocks.
79	21	Metal for bearings.
67	33	Very hard alloy, which forms the extreme limit of the ordinary tin-antimony alloys (*Hiorns*).

Babbitt Metal.

This alloy, whose composition is as follows:—Tin, 83·3; Antimony, 11·1; Copper, 5·6; is used on important bearings under heavy loads, such as crank-shaft, crank-pin, and cross-head pin journals.

Several of the French railways use the following alloy, which is low in tin:

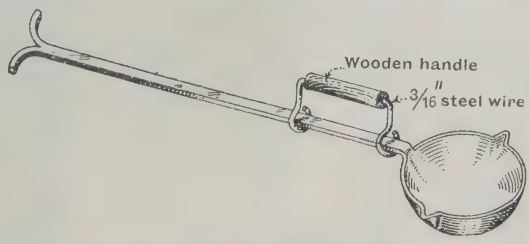
Tin, 67; Antimony, 22 to 11; Copper, 11 to 22.

In cast-iron boxes, for light work: 50 parts tin, 5 parts antimony, 1 part copper; for heavy work: 46 parts tin, 8 parts antimony, 4 parts copper. In brass boxes: 64 parts copper, 8 parts tin, 1 part zinc. The bearing to be lined with the metal is first tinned with the Babbitt metal mixed with twice its weight of tin.

Babbitt metal should be stirred thoroughly from the bottom of the pot at frequent intervals when being used, to prevent segregation of the constituents. If the pot is used only occasionally, the Babbitt should be covered with sawdust to prevent the formation of dross.

Pouring Babbitt Metal.

A convenient auxiliary handle that can be fitted to any Babbitt ladle is made from a short length of wooden bar, such as a piece of broom handle, drilled through for a piece of heavy wire or



¼-in. round rod, which is bent around the ladle handle as shown, so that it is loose enough to slide up and down readily.

(*H. Moore*, '*Power*,' *Aug.* 21, 1928.)

Babbitt Metal, Plastic Metal, and Phosphor Bronze.

These metals are supplied by the Delta Metal Co. Ltd., in various grades; phosphor bronze is supplied in three qualities, A, B, and C. The A quality is a hard bearing metal specially suitable for worm-wheels, bushes, crank pins, bearings, etc.; B quality phosphor bronze is a bearing metal more suitable for general purposes; whilst the C grade is adapted for large pinions, worms, etc. The Company also supply various grades of Babbitt, plastic, and other lining metals, for various speeds and pressures.

Admiralty White Metal.

Tin, 86·0; Antimony, 8·5; Copper, 5·5.

ALLOYS HAVING A LEAD BASE.

Lead-Antimony Alloys.

These alloys should not contain more than 18 per cent. of antimony if they are not to be brittle. Such as do contain upwards of 18 per cent. of antimony must be given suitable support. The following table indicates the increase of Brinell hardness numbers of these alloys with increase of antimony.

Antimony. Per cent.	Brinell Hardness Number. 10 mm. 100 kilos.

N.O.—Not observed. C.—Cracks in compression test-piece.
S.C.—Slight cracks in compression test-piece. * Failed without compression to half length.

The results contained in this table are considered sufficient to merit the following conclusions: (1) that the effect of the presence of the tin antimony compound in these alloys is such as to render the same brittle and weak; (2) that the general mechanical properties of the lead-tin-antimony alloys containing less than about 15 per cent. of tin are improved by the addition of antimony in quantities not exceeding about 10 per cent.

Hughes recommends the following alloy for metallic packings :—
Lead, 70 ; Antimony, 13 ; Tin, 17;
while the following alloys are used as lining by the Eastern Railroad of France :—

	Lead.	Antimony.	Tin.
1 . .	70	20	10
2 . .	80	8	12

1. For eccentric straps and bronze slide valves.
2. Special alloys for metallic rod packing.

Ternary alloys of lead, antimony and copper are also in use. These alloys should contain from 15 to 25 per cent. of antimony and not more than 10 per cent. of copper.

Anti-Friction Alloys.

Delta Anti-Friction Alloys.

(The Delta Metal Co. Ltd.)

Delta White Anti-Friction Metals, Nos. IX and IXa, are used for lining bearings, bushes, etc., and are particularly suitable for heavy bearings such as those of marine engines, for railway trucks, dynamos, etc., as they do not wear, heat, or cut the journals ; they are also cheap.

The application of the metals presents no difficulties whatever ; the parts required to be lined should be thoroughly cleaned, and when the metal is melted (which may be done in a ladle, over a slow fire, taking care not to overheat it) it is applied in the usual way. The melting point is about 450°C.

Fry's Anti-Friction Alloys.

(Fry's Metal Foundries, Ltd.)

These anti-friction alloys cover the whole range of white metals employed in engineering practice ; commencing with lead-free alloys of high tin content with sufficient antimony and copper to provide necessary hardness and wearing qualities combined with great toughness (as in the O1 brand) which are used for special service, as in the big end bearings of engines for aircraft or high-powered cars, and ending with the finest quality of lead-base alloys of the Magnolia class.

The series includes bearing metals suitable for every class of service, heavy and light loads, high speeds and slow-running machinery, and plastic metal for emergency and special services. The high-tin alloys are self-tinning. All but the first alloy in the series have a structure consisting of a matrix of tough and durable alloy with cuboid antimony-tin crystals regularly embedded throughout. The first is a tin-antimony solid solution with crystals of copper-tin and copper-antimony constituents interspersed in dendritic or needle-shaped formation. The constituent of dendritic crystal form is actually present in all well-balanced alloys of this character, adding greatly to their toughness and durability, and also serving to ensure the even distribution of the cuboid antimony-tin constituent. Finally, hard and highly resistant zinc-tin rock crusher bearing metal of great endurance can be furnished.

The following table shows a selection of bearing metals for particular purposes and for design work :

Constituents, per cent. A = Tin; B = Antimony; C = Copper; D = Lead.					Tensile Test.		Brinell Hardness. Number. 10 mm. Ball 500 Kilos.	Compression Test. Tons per sq. in.

ZINC-TIN ALLOYS.

Zinc and tin form a series of eutectiferous alloys, some of which are of value as bearing metals. The alloys, in common with all bearing metals, are very susceptible to differences in casting

temperature, as may be gathered from the following table, which gives in detail the effect of varying the temperature of casting an alloy of 70 per cent. of zinc and 30 per cent. of tin :—

Casting Temperature.	Maximum Stress.	Elongation. Per cent.	Stress to compress to half length.
525° C.	5·09	3·0	7·7
500° C.	6·17	3·0	13·6
475° C.	6·56	8·0	15·4
450° C.	7·37	17·5	14·8
425° C.	7·37	35·5	15·0
400° C.	7·24	20·0	15·8

The above figures are for chill castings.

The alloys of zinc and tin containing from 25 to 75 per cent. of zinc possess, when in the chill cast condition, tenacities varying from 6·0 to 6·5 tons per square inch, percentage elongations varying from 30 to 45, and are compressible to half-length under stresses (calculated on the original areas of the test-pieces) varying from 13 to 17 tons per square inch. The eutectic melts at about 200° C. and contains 16 atomic per cent. of zinc.

In order that these alloys may approximate more closely to type A (*q.v.*) bearing metal, the zinc-tin series containing no relatively hard constituent, copper and antimony are frequently added. The addition of one or both of these constituents results in the formation of a bearing metal in which the hard compounds of antimony and zinc, etc., are indiscriminately distributed throughout the eutectiferous matrix. The following are analyses of certain alloys of this type :—

Zinc.	Tin.	Copper.	Antimony.	Use of Alloy.
80	14·5	5·5	—	Fenton's alloy for locomotive axle-boxes.
69	26·0	5·0	—	Propeller bush.
88	2·0	8·0	2·0	Bearing metal for general use.

In this connection it may be noted that ternary alloys generally are far preferable to complicated mixtures and usually fulfil all the requirements of good bearing metals.

A French report on new anti-friction metals includes trials of alloys consisting chiefly of aluminium, cadmium, magnesium, and especially of zinc. Such alloys were designed to reduce as far as possible the use of copper, tin, lead, and antimony, and the most satisfactory results are stated to have been given by a compound of 63·3 per cent. of zinc, 21·3 per cent. of tin, 12 per cent. of lead, and 3·3 per cent. of copper.

FUSIBLE METALS.

With the following combinations of metals, which form 'eutectiferous' alloys, it is possible to prepare an alloy having a melting point lower than that of any member of the series.

Series.	Alloy with Lowest Melting Point (Eutectic).	Melting Point.
Bismuth-lead	57·4 per cent. Bismuth	124·5° C.
Bismuth-tin	56·7 ,, ,,	137° C.
Bismuth-cadmium	60 ,, ,,	146° C.
Cadmium-tin	52 ,, Cadmium	177° C.
Lead-tin	36·5 ,, Lead	180° C.
Cadmium-lead	17·4 ,, Cadmium	247·3° C.

By the addition of one or both of the residual metals to any of the above combinations, systems of ternary and quaternary alloys, having individual members with melting points lower than those of all other members of these systems and less than those of the eutectics given above, may be obtained. These ternary and quaternary alloys are the true 'fusible metals.'

The alloys of lead, tin and bismuth are of value for the following purposes :—

(i) The manufacture of casts of delicate objects that would be damaged if subjected to high temperatures. The following alloys are recommended for this purpose :—

Bismuth	59·2	50·0	50·0	50·0
Lead	27·3	31·2	30·0	25·0
Tin	13·5	18·8	20·0	25·0

These alloys expand considerably on cooling and are valuable also for the taking of impressions from dies, medals, etc.

(ii) Fusion pyrometers. Parkes and Martin recommend the following fusible metals as pyrometers for the tempering of steel tools. The article to be treated is placed on a plate of the alloy, which is heated till it melts. The tool, being then in the required condition, is quenched in water.

Table of Melting Point of Bismuth-Lead-Tin Alloys.

Bismuth.	Lead.	Tin.	Melting Pt.	Bismuth.	Lead.	Tin.	Melting Pt.
50·0	31·2	18·8	94° C.	16·6	33·2	50·2	158° C.
47·0	35·5	17·7	98° C.	16·0	36·0	48·0	155° C.
42·1	42·1	15·8	108° C.	15·3	38·8	45·9	154° C.
40·0	40·0	20·0	113° C.	14·8	40·2	45·0	153° C.
36·5	36·5	27·0	117° C.	14·0	43·0	43·0	154° C.
33·3	33·3	33·3	123° C.	13·7	44·8	41·5	160° C.
30·8	38·4	30·8	130° C.	13·3	46·6	40·1	165° C.
28·5	43·0	28·5	132° C.	12·8	49·0	38·2	172° C.
25·0	50·0	25·0	149° C.	12·5	50·0	37·5	178° C.
23·5	47·0	29·5	151° C.	11·7	46·8	41·5	167° C.
22·2	44·4	33·4	143° C.	11·4	45·6	43·0	165° C.
21·0	42·0	57·0	143° C.	11·2	44·4	44·4	160° C.
20·0	40·0	40·0	145° C.	10·8	43·2	46·0	159° C.
19·0	38·0	43·0	148° C.	10·5	42·0	47·5	160° C.
18·1	36·2	45·7	151° C.	10·2	41·0	49·5	161° C.
17·3	34·6	48·1	155° C.	10·0	40·0	50·0	162° C.

(iii) Soft solders. For the union of metal to glass, *e.g.* in the manufacture of paraffin lamps, the following alloy has been suggested :—

Lead, 40·0; Bismuth, 33·4; Tin, 26·6.

(iv) Fusible plugs.

The above alloys are nearly all of a brittle character. For the manufacture of ductile fusible alloys the use of cadmium in place of bismuth is recommended.

The following table includes the best known of the other fusible metals :—

Alloy.	Cadmium.	Lead.	Tin.	Bismuth.	Melting Pt.
Fusible alloy . .	12·5	25·0	12·5	50·0	55·5° C.
Lipowitz's alloy .	10·0	26·6	13·3	50·0	60–68° C.
Woods' alloy . .	15·4	30·8	15·4	38·4	71° C.
Fusible alloy . .	34·5	27·5	10	27·5	75° C.

,, ,, . .	11·1	—	33·3	55·6	95° C.
,, ,, . .	25	—	25	50	95° C.

Spence's Metal.

This compound is obtained by melting the three sulphides of iron, zinc and lead with sulphur. The product is a dark grey mass of great tenacity, small power of conducting heat, a specific gravity of 3·4, a melting point of 160° C. In congealing it expands like bismuth and type metal, and resists in a remarkable degree the action of atmospheric influences, alkalies and acids, even of aquaregia, its surface scarcely being affected after having been exposed to the action of the latter for four weeks. Its property of expanding in congealing, and therefore filling completely all depressions of the mould, makes it particularly available for castings. If the compound is poured on a plate on which the impression of the hand has been made, the cast will show all the lines and the pores of the palm.

The metal has been used for jointing gas and water pipes.

For further particulars see Patent Specification No. 2706, 1879.

Type-Metal.

Metal.	Tin.	Antimony.	Lead.

Rotary Plates	6% ,, 10%	15%	,,

The addition of Copper to type metals as an extra hardener is generally discontinued. Small quantities creep in during repeated remelting. Quantities above 0·12 per cent. are apt to give trouble in machine composition work.

Non-Magnetic Alloys.

These alloys are used as substitutes for steel wherever it is employed in the works of watches. The composition of the alloys varies from 45 to 75 parts of palladium, 15 to 30 parts of copper, 20 to 25 parts of silver, with sometimes the addition of small proportions of iron, steel, nickel, gold and platinum. These alloys are claimed to be unoxidisable in moist air, to preserve their elasticity indefinitely, not to vary sensibly with changes of temperature, and to remain uninfluenced by proximity to dynamos.

Another non-magnetic alloy, recently brought out by Messrs. Ostermann & Lacroix, of Geneva, Switzerland, is made of from 30 to 40 parts of gold, 30 to 40 parts of palladium, 0·1 to 5 parts of

rhodium, 10 to 20 parts of copper, 0·1 to 5 parts of manganese, and the same proportions of silver and platinum. The copper and manganese are first mixed, after which the other articles are added; or all the metals may be put into a crucible at the same time, the manganese being used for the bottom layer.

A non-magnetic variety of 'Bull's Metal' is manufactured and sold as No. III. and is being adopted for funnels and other erections of warships where the material must possess the mechanical properties of steel without its magnetic influence.

The Delta Metal Co. Ltd., supply under their 'Delta' Brand non-magnetic metals (bronze and brass) to meet special requirements.

SOLDERS AND SOLDERING.

The following notes are published with the kind permission of the Editor of 'The Metal Industry.' (See 'The Metal Industry,' vol. 9, No. 4.)

Points to be Observed for Successful Soldering.

Attention should be paid to the following points if success is to be attained in soldering or brazing :—

1. In the preparation of the solder, uniformity of composition should be aimed at. Readily volatile or oxidisable constituents should be retained.

2. In the choice of the solder, consideration should be taken of the fusibility of the solder. The melting point of the solder should be less than that of the metal to be soldered. It should be noted, however, that the more nearly the melting point of the solder approaches that of the metal to be soldered the better is the union obtained, although the more difficult is the operation of soldering. It should be considered whether the solder will mingle perfectly with the surfaces to be united. One having mechanical and physical properties as nearly as possible approximating to those of the metals to be united should be used. One whose mechanical and physical properties will not be subsequently modified by any treatment—thermal or otherwise—should be employed.

3. In the operation of soldering, thorough mechanical and chemical cleanliness of the surfaces to be united must be obtained, e.g. by scraping, filing, grinding, etc., and by dipping in suitable chemical reagents. A source of heat both smokeless and sufficiently hot to raise the temperature of the sections to be united above the melting point of the solder is necessary. A suitable flux must be used.

Fluxes.

Fluxes are used to protect the surfaces of the metal to be united from the oxidising action of the atmosphere during the process of heating. The presence of any non-metallic materials, such as oxides or carbonates, on the surfaces to be joined, effectually prohibits perfect union. As the process of heating a metal in the air always leads to the formation of a film of oxide on its surface, means must be employed to protect the surface. Use is made of readily fusible salts and of oils that are non-volatile at the temperature of soldering for this purpose. For hard-soldering borax is practically the only flux employed. It is applied as a paste with a brush to the surfaces of small articles, and as a powder to those of larger articles. For soft-soldering a variety of materials is used, the following list giving the most important of these, together with their uses.

(i) Zinc chloride is used for the soldering of sheet metal, copper alloys and bright iron. It is poisonous and corrosive, and is on these accounts unsuited (*a*) for the soldering of tins destined to contain food, and (*b*) for the production of delicate work, e.g. electric fuses.

Zinc Chloride Solution.

Kill 2 quarts hydrochloric acid with all the zinc it will take up. Add a quart of water or add part until zinc is fairly dissolved. A quart of glycerine which has been mixed with a quart of alcohol is then added to the solution.

This fluid is used for all kinds of soldering, especially with greasy and dirty connections and iron. It is claimed that glycerine prevents rust, which plays havoc with other soldering solutions containing hydrochloric acid. (*Street Railway Journal.*)

Zinc Chloride Paste.

1 lb. vaseline or petrolatum ; 1 oz. (fluid) saturated solution of chloride of zinc.

The use of petrolatum instead of vaseline is recommended. While they are identical in composition, the name 'vaseline' is registered as a trade-mark, and commands a higher price on this account. Petrolatum is much cheaper. The chloride of zinc solution is made by dissolving as much zinc in strong muriatic acid as it will take up. An excess of zinc should be present, and all the acid neutralised. This will form a thick, oily solution. The petrolatum and chloride of zinc are mixed and thoroughly incorporated by means of a mortar and pestle or by vigorous stirring. The advantage of this soldering paste lies in the fact that it does not spatter and is not corrosive.

(ii) Ammonium chloride is used as a flux when soldering copper and iron.

(iii) Ammonium phosphate is used when treating with tin, zinc, copper and brass ware. It is non-corrosive and non-poisonous, but is somewhat refractory.

(iv) Hydrochloric acid is employed when dealing with zinc and zinc-coated ware.

(v) Lactic acid is useful in connection with copper and its alloys, but has the disadvantage of producing a tarnish on the surfaces adjacent to the soldered surfaces.

(vi) Venice turpentine and Gallipoli oil are used (separately) when soldering pewter or Britannia metal.

(vii) Russian tallow is employed when soldering heavy lead work.

(viii) Palm oil is employed in the treatment of light lead work.

(ix) Resin is an advantageous flux when subsequent corrosion is likely to be deleterious. It is used on soft alloys and tinware.

Hard Solders.

The hard solders may be divided into two groups, each of which will be considered separately in succeeding paragraphs—brazing or 'spelter' solders and silver solders.

Brazing or 'Spelter' Solders.

The basis of the brazing or 'spelter' solders ('spelters' they are commonly called) is brass. As the percentage of zinc is increased in the brasses so does their utility as solders for the more readily fusible metals and alloys increase. There is, however, a limit beyond which the addition of zinc to these alloys serves no useful purpose, owing to the fact that the resulting alloys are, on account of their brittleness and weakness, of no practical value. This limiting value is at about 45 per cent. of zinc. The particular alloy which is in most general use contains 50 per cent. of zinc and melts at about 875° C. (1607° F.). It is employed in brazing general brass work, which is possessed of melting points varying from about 890° C. (1634° F.) to about, 1000° C. (1832° F.). For brazing metals, etc., having higher melting points than the above brasses containing a less percentage of zinc are used. Thus, for the soldering of general ironwork the brass containing 35 per cent. of zinc is used, while for the brazing of copper and light ironwork that having 40 per cent. of zinc is employed. The most malleable solder contains some 30 per cent. of zinc, but its refractory nature somewhat subtracts from its value.

For certain purposes, the above alloys, owing to their yellow colour, are prohibited. Occasionally—e.g. in the brazing of nickel silver and iron—whiter alloys are required. For this purpose alloys containing nickel are employed, of which the following are examples :—

Copper per cent.	Zinc per cent.	Nickel per cent.
37·50	50·00	12·50
35·00	57·00	8·00

Other white solders, for use in the brazing of brass and more fusible than 'spelters,' contain a percentage of tin. Two such solders are given below :—

Copper per cent.	Zinc per cent.	Tin per cent.
43·34	6·66	50·00
57·50	25·00	17·50

The British Engineering Standards Association has issued a Specification (No. 263—1926) covering two grades of brazing solder. The copper contents for the two grades range from 53 to 55 per cent. and from 49 to 51 per cent. respectively, maximum limits being specified for the tin, antimony, arsenic, bismuth, iron and lead permitted in the alloy. A table is included as an appendix to the specification giving a range of grain sizes of granular solder to which it is recommended that the material be ordered.

Silver Solders.

Silver solders are employed for soldering gold, silver, copper, iron, and their alloys, the flux generally used being borax, though with very hard solders—*i.e.* solders having high melting points—powdered glass is sometimes of value.

Such as are suitable for general soldering and brazing, and containing an excess of base metal, are tabulated below :—

Copper per cent.	Silver per cent.	Zinc per cent.	Uses.
90—95	10—5	—	Solder for thin sheets of mild steel.
55·0	45·0	—	Alloy for instrument-makers ; tough and fluid.
50·0	30·0	20·0	Solder for small brass work.
46·0	38·5	15·5	Solder for bronze and nickel silver.
43·0	9·0	48·0	Solder for general work on copper alloys.

Tin-Lead Solders.

Tin and lead form a series of alloys, of which only those containing upwards of 35 per cent. of lead are employed as solders. These alloys may be divided into two classes, those that solidify at practically one definite temperature and those which are pasty over a considerable range of temperature before they become completely solid. The former are used as tinmen's solders, the latter as plumbers' solders, their value to each of these craftsmen being dependent on the properties associated with their solidification already mentioned. The diagram on page 2750 indicates the ranges of composition of the two types of solder already mentioned.

It will be seen that fine tinmen's solder solidifies at a definite temperature of 180° C. (356° F.) while coarse tinmen's solder commences to solidify at about 209° C. (408° F.), passes through a pasty stage, and finally completely solidifies at 180° C. (356° F.). Soft solder is the name given to the alloy containing 50 per cent. of lead, whilst the fine plumbers' solder, used in making 'wiped' joints, which commences to solidify at about 250° C. (482° F.), contains 66·6 per cent. of lead. A solder frequently used for the union of tinplate contains about 90·0 per cent. of lead, and hence has a very marked pasty range of temperature.

The appearance of the tin-lead solders affords some idea as to their value. The surface of good solder should be smooth and even, and rectangular castings of the same should have a distinct furrow along the centre of their upper surface. The presence of zinc, though only traces of this metal be present, causes the free surface of the solder to become minutely crystalline.

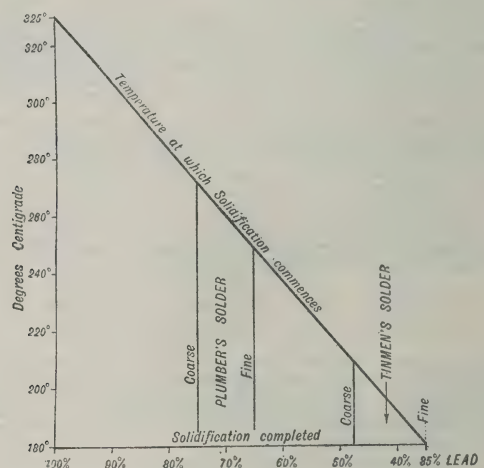

Diagram illustrating the approximate Range of Solidification of the Lead-Tin Alloys.

Bismuth, copper, and silver do not affect the surface condition of solders when present in quantities varying from 0·2 per cent. in the case of the last metal to 1·0 per cent. in the case of the first, while antimony up to 2·0 per cent. improves, rather than otherwise, the surface condition. The presence of any of these elements leads to a reduction of the melting point of the solder.

To Prevent Solder Sticking to Work.

To prevent hot solder sticking to work, mix common whiting or cold-water paint with wood alcohol, and paint the part that is to be protected. The hot solder will not stick, even if the piece is held in the melted alloy. Water will do as well as alcohol to mix the paint; but alcohol is the most convenient, inasmuch as it can be used without waiting for the paint to dry. If water is used the paint must be thoroughly dry, as otherwise the moisture will cause the solder to fly.

Bismuth Solders.

These solders are alloys of bismuth, tin and lead, and are in general more fusible than the tin-lead solders. The useful alloys contain from 20 per cent. to 65 per cent. of lead, from 12 per cent. to 55 per cent. of tin, and from 12 per cent. to 55 per cent. of bismuth. The alloys containing the higher percentages of bismuth are the most fusible of these solders, which are employed for general pewtering. The solder containing about 50 per cent. of bismuth and 20 per cent. of tin has the lowest melting point of the series, its value being 96° C. (205° F.).

Aluminium Soldering.

Success in soldering aluminium depends on the effective removal from the metal of the microscopically thin film of oxide always present on the surface. When measures are taken to deal with this film the main difficulty of soldering is removed. Three different types of soldering are employed, which may be distinguished by the terms hard soldering, soft soldering, and reaction soldering.

Hard Soldering.

In this process the solder consists of an alloy of aluminium having a melting point between 500 and 600° C. Many such alloys exist but the silicon alloy, containing 10 to 13 per cent. of silicon, is undoubtedly the best. The oxide is removed by means of an alkaline halide flux, such as is used for aluminium welding. At the temperature at which the soldering is carried out the flux is melted and rapidly attacks the oxide, permitting the melted solder to come into contact with clean aluminium and alloy with the surface. In carrying out the process a gas blowpipe is used as heating medium, but apart from this and the high temperature required, the process does not differ from the ordinary soldering of brass. The flux is applied on the end of the solder stick, which is melted up and flows readily, sweating the parts together. It is necessary to see that the edges to be soldered are properly hot, and in some cases it will be found convenient to heat them first until they are hot enough to melt the solder stick when the latter is rubbed on them. Certain manufacturers supply silicon alloy solder in the form of a tube with the flux contained inside.

Hard soldering with a silicon alloy solder is thoroughly to be recommended as regards ease of application, strength, and permanence. Unlike soft soldering, the joint is capable of withstanding the action of boiling water or steam without protection.

Soft Soldering.

In this process the solder melts at a comparatively low temperature, and it is this type of work which has given rise to the widespread view that aluminium is difficult to solder. The reason is that no satisfactory flux is available which will attack the oxide at the low temperature of working, so that the oxide must be removed by mechanical means. After a preliminary cleaning, the metal is heated until the solder melts upon it. The molten solder will not adhere but it can be made to do so by scraping through it with an old hacksaw blade or other form of scraper to break up the oxide film. Once the film is broken the oxide cannot reform under the solder, and alloying takes place. When the surface is fairly well covered with molten solder the adhesion is improved by rubbing with a wire scratch brush while still molten, thus breaking up any remaining traces of oxide. After such 'tinning' the parts can be sweated together in the ordinary way. Fluxes are sometimes supplied with these solders but these consist largely of stearin or resin and are of little assistance.

The composition of the solder is not of great importance. It usually consists of zinc and tin with or without small additions of other ingredients. The best compositions as regards permanence are those with high percentages of zinc, though these are of higher melting point and are therefore not so readily applied.

Reaction Soldering.

This is a newly developed process which is particularly interesting. The solder is a chemical mixture containing halides and zinc chloride, which is spread on the parts to be jointed and heated by a blowpipe to about 200° C. A chemical reaction takes place which results in the deposition of pure zinc in a molten condition on the aluminium surfaces to be joined. The zinc flows readily between the edges and alloys readily with the aluminium, forming an excellent joint. Such joints are much more permanent than joints made by the ordinary soft soldering process.

Cold Solder (Amalgam Solder).

By shaking finely-divided copper with mercury in a little dilute sulphuric acid an amalgam can be prepared which may be used to unite joints at ordinary temperatures. The amalgam is formed into pellets, which are heated till mercury begins to exude from the surface. These pellets are wiped free from mercury and are then rubbed to a soft paste in a mortar. The surfaces to be united are first treated with sodium amalgam (sodium 2 per cent.), the soft paste of copper amalgam being then applied. The surfaces to be joined are then tightly pressed together, the union being completed in about three hours.

Soldering Aluminium Bronze.

To solder aluminium bronze with ordinary soft (pewter) solder : Cleanse well the parts to be joined from dirt and grease. Then place the parts to be soldered in a strong solution of sulphate of copper, and place in the bath a rod of soft iron, touching the parts to be joined. After a while a copper-like surface will be seen on the metal. Remove from bath, rinse quite clean, and brighten the surfaces. These surfaces can then be tinned by using a fluid consisting of zinc dissolved in hydrochloric acid in the ordinary way with common soft solder If the surface is not coppered an aluminium alloy must be used.

Soldering Cast Iron.

(1.)

If the part of iron to be soldered is cast iron that is hard and thin, it should be polished on an emery wheel and made clean and bright. Then dip it in potash water, after which dip it for an instant in clean water, and wash quickly with undiluted hydrochloric acid of the ordinary strength ; go over it with powdered resin and solder made from half tin and half lead. This must be done quickly, before the surface has time to dry.

(2.)

File the surface clean, and wash as before ; wipe it over with a flux made of sheet zinc dissolved in hydrochloric acid until it is surcharged, or is a saturated solution and has been diluted with its own quantity of water ; then sprinkle powdered sal ammoniac on it, and heat it on a charcoal fire until the sal ammoniac smokes. Dip it in melted tin, and then remove, and rap off the surplus tin.

CASTING AND FOUNDING.

Moulding-sand.*

(1.)

1 cubic foot sharply burnt and pulverised pure fire-clay ; 60 cubic inches sugar ; 2 quarts water ; ½ quart paraffin oil. No lime or charcoal must be included in the mixture. Thoroughly mix. Suitable for castings of ingot iron.

(2.)

93 parts pure quartz sand ; 7 parts clay free from lime ; the latter acts as a cement for the former.

(3.)

For small castings :—Red sand, 3 parts by measure ; coal dust (finely sifted), 1 part by measure.

(4.)

For large castings :—Red sand, 3 parts by measure ; coal dust (finely sifted), 1 part by measure ; chopped straw, or dried horse manure, ½ part by measure.

The latter makes the sand light and porous, facilitating the release of the gases. As the sand becomes impoverished by being burnt, the coal dust is renewed from time to time. If paraffin is used to damp the mould, black sand will bind and can then be dried as when red sand is used.

Moulding-sand which has partially lost its cementing power may have it restored by mixing with fresh sand.

Green, or floor sand that has ' gone dead ' (dehydrated) is frequently revived with Birmingham or Mansfield sand. Bunter sand, and also Barrow sand, have been found very good for the same purpose.

When the metal touches the clay bond the clay is undoubtedly killed, but not so the ferruginous bond, and long-life sand is generally rich in the latter.

Ferruginous bond in moulding sand is usually the cause of the production of a smooth, sound surface to the casting, particularly in the case of steel. In non-ferrous practice it is usual to ensure the smoothness of the skin by painting the surface of the mould or ' facing ' it with a layer of finer sand (facing sand) or a wash.

The washes used for painting the mould in non-ferrous work have usually either china clay or a graphitic substance as base. Graphite (plumbago) is itself used at other times. ' Scotch blacking,' which is a mixture of charcoal and graphite, is employed.

A suspension of the powder in water may be assisted by the addition of a little borax or molasses.

---

* For further information on Moulding Sands see ' Sands and Crushed Rocks,' by *A. B. Searle* (*Oxford University Publications*).

Cores.

For the making of 'cores' in British foundries a 'compo' moulding sand is made from ordinary sand such as Mansfield and broken fragments of graphite crucibles ground and mixed.

The admixture of the coarser material ensures good venting of cores; at times the sand alone is used.

Oil-bonded cores (where the oil is generally a commercial linseed, such as 'Baltic seed oil'), unlike those used in steel founding, have not met with much success in non-ferrous founding at home, but are adopted extensively in America, where a fairly coarse high-silica sand is the base. Sands from Lumberton and Howell, N.J., are so used. (*Horobin.*)

Moulding Sands.

Sand.	Moisture Content. %	Green Bonded Strength.		Traverse Strength. Lbs.	Permeability. Secs.
		Riddled. Ins.	Milled. Ins.		
Green facing sand .	7·6	2·3	2·4	—	120
Dry facing sand .	8·5	2·5	2·8	3·0	99
Black . . .	7·5	1·8	—	0·75	141
Red . . .	10·1	2·3	—	2·25	86

Core Sand Mixtures.

Mixture.	Moisture Content. %	Transverse Strength. Lbs.	Green Bonded Strength. Ins.	Permeability. Secs.	Remarks.
Ordinary core sand	8·2	2·25	2·3	106	Not free venting, but can be handled in the green state
Sea-sand 20 parts to 1 part linseed-oil	5	65	1·2	46	Cannot be handled in undried state.
Sea-sand 40 parts to 1 part linseed-oil	5	28	1·1	43	Suitable for most ordinary work
Leighton Buzzard 20 parts to 1 part linseed-oil	5	53	1·1	28	Binds better with treacle than linseed-oil
Leighton Buzzard 40 parts to 1 part linseed-oil	5	22	0·75	23	

Testing Moulding Sands.

Methods of testing moulding sands are described in 'Sands and Crushed Rocks,' by A.B. Searle (Oxford University Publications). A rough-and-ready test for voids and porosity consists in putting 50 c.c. of water in a glass measuring cylinder and 50 c.c. of the sand (previously passed through a 12-mesh sieve) into a graduated glass cylinder holding 100 c.c. The water is added to the sand and the cylinder with its contents is violently shaken until the water and sand are thoroughly mixed. The mixture is allowed to settle and the total volume is then measured. The reduction in volume is a measure of the volume of voids or pores in 50 c.c. of the sand.

By watching carefully, the time taken for the grains of different sizes to settle may also be noted.

To Repair Castings by Burning on.

A piece of machine-framing, the necks of rolls, or a standard which has been broken or found defective, may be repaired as follows: First cut away the defective parts down to the sound metal; build a coke fire round the part of the casting which is to be repaired until it is brought to a bright red-heat, then dust over the surface of the cut metal with powdered glass or borax. Then apply a hollow loam mould of the desired part to the casting, properly secured in position and provided with a hole for the exit of the metal. Pour very hot liquid cast iron into the mould, and allow it to flow away until the cut surface of the original metal of the casting can be felt with an iron bar to have become soft and pasty by contact with the hot liquid iron. Then stop the exit hole and allow the metal in the mould to set. If the operation has been properly performed the casting should, when struck, ring with the same sound as a single good casting, thus showing that the old and new metal are perfectly united.

Sealing up Cracks in Castings and Cementing Joints.

Cracks in the walls of pressure vessels may be patched by bolting on a plate with a thickness of sal ammoniac and iron borings beneath it. Many an external firebox sheet has been patched in this way.

A cast-iron cylinder for a hydraulic press in which the iron was so porous that, under 2,000 lb. pressure, the water ran down the outside in rivulets, has been sealed by filling the cylinder with water containing a large quantity of sal ammoniac and letting it stand for a couple of days. At the end of that time the cylinder was perfectly tight.

The sal ammoniac treatment has been used in railway shops for stopping cracks in bushing cylinders. In one instance an 18 × 22 in. cylinder was patched that way. It was an old cylinder that had been bored out and a cast-iron bushing inserted. A coat of white lead was spread on the outside of the bushing and after it was in place it was stayed to the cylinder wall by drilling holes through the wall and bushing and screwing in brass plugs. Some time later a crack running lengthwise between the plugs in the outer shell opened up for about 15 in. This was made tight by removing the piston, closing the ends of the cylinder and pouring a sal ammoniac solution through the ports until the cylinder was full. This was allowed to stand for ten days, then the cylinder was drained and refilled with a weak solution of muriatic acid and allowed to stand again for about ten hours. The purpose of the muriatic-acid solution was to complete the work begun by the sal ammoniac. It was presumed that the acid would cut away the coating of rust produced by the sal ammoniac, and that the particles would gravitate toward the pressure. And apparently this is what happened.

White lead has been used with advantage in making up threaded pipe joints and when pressing the brasses into locomotive driving boxes, placing driving pins in the wheels, etc. In the latter case the white lead acts as a lubricant while the job is being done, and later on, after it has set, it serves to cement the part pressed in. For many uses red lead is preferable to white, and next to litharge, is best for holding anything. If a threaded pipe joint is made up, say a 2 in., with white lead, after a year's time it will still be possible to remove the fitting, but if the same fitting is made up with red lead, and it is desired to take it off after the lead has hardened, the fitting will have to be broken unless sufficient heat can be applied to cause it to loosen from the pipe.

There is no cementing effect when graphite and oil is used on a pipe thread. With graphite and oil on a thread a fitting can be made up tighter than would otherwise be possible. Also, the graphite is squeezed compactly into the interstices in the joint and its very compactness holds it against blowing out under pressure, but it does not anchor the fitting. Therefore, no greater stress is necessary to remove the fitting at any time than was used to put it on.

Litharge will make a threaded pipe joint absolutely leak-proof against any kind of fluid and against any pressure that the pipe will stand.

(*Power, July* 1, 1924.)

Pattern Composition

A composition that has many advantages over wood for making small patterns can be made as follows:—With hot water mix into a thick paste three parts by volume of starch, one part ground glue, two parts fine resinous sawdust. The sawdust should not be added until the starch and glue have been dissolved by the water. After the ingredients are thoroughly mixed, heat the whole to 190° F., and continue the heating until the whole becomes a hard mass, then allow to cool, and remove from the receptacle. The resulting composition is a strong, hard, horn-like substance, that can be machined, sand-papered and varnished just as can wood. The principal advantages of this composition over wood lie in the fact that it has no grain, and therefore turned and complicated patterns made from it do not have to be built up or glued together, and that for the same reason it is easier to turn and machine, and offers a smoother surface when finished. It is also more fireproof than wood and not so readily affected by atmospheric changes.

(*American Machinist.*)

Shrinkage of Castings.

The allowance for shrinking in casting should be for each foot in length :—

	Parts of an Inch.		Parts of an Inch.
For cast-iron pipes	·125 = $\frac{1}{8}$	Brass	·17 = $\frac{3}{16}$
„ beams and girders	·1 = $\frac{1}{10}$	Lead	·31 = $\frac{5}{16}$
„ cylinders, large	·094 = $\frac{3}{32}$	Zinc	·25 = $\frac{1}{4}$
„ small	·06 = $\frac{1}{16}$	Copper	·17 = $\frac{3}{16}$
In thick breadth	·156 = $\frac{5}{32}$	Tin	·25 = $\frac{1}{4}$
In thin breadth	·156 = $\frac{5}{32}$	Bismuth	·156 = $\frac{5}{32}$

Cleaning Castings.

A large proportion of the loose sand on castings may be removed in the 'tumbling' process, but the adhering sand and scale of oxide, which soon destroy the cutting edge of the tools, are best reduced by a pickle; the following have met with general approval.

Sulphuric Acid Pickle.—Ordinary commercial sulphuric acid and water in the proportion of 1 of the former to 30 of the latter. In this case the castings are required to remain in the pickle for about 10 hours, and are then washed with hot water to remove all trace of the acid and prevent rusting.

Hydrofluoric Acid Pickle.—This acid is slower in its action and not so liable to cause corrosion as the above. The castings, however, should be first tumbled in order to remove loose sand (as the sand neutralises the solution very much more quickly than the iron) and then immersed in a mixture containing 1 of hydrofluoric acid to 15 of water. The bath should be maintained at a temperature of 120°F. by a steam coil. The castings are then washed in clean hot water and sometimes in hot water with a small proportion of lime (about 1 lb. of lime to 8 gallons of water).

The baths are best made of oak, wood pinned, with no exposed metal fastenings and well lined with asphaltum. The attendant should be furnished with wooden clogs, strong leather apron and rubber gloves to protect him from the acid.

The acid should be added *very slowly* to the *water* and well stirred in the process. Never add the water to the acid, otherwise the acid vapour will be carried all over the place.

An American factory is using high-pressure water for cleansing castings of sand and cores. A centrifugal pump, driven by a 50-h.p. motor, delivers 250 gallons per minute at a pressure of 250 lb. per sq. in., and the work is carried on in a closed chamber with glass windows. It is said that a casting which previously took a whole day to clean can be finished with the water jet in half an hour.

(See also 'Lubrication Troubles,' p. 988.)

Dips for Castings.

Special for Electro-galvanising.—For preparing work for electro-galvanising the following can be used with advantage, but for no other solution except, perhaps, copper : Add to the dilute acid ½ lb. of sheet zinc to each 25 gals. of solution, adding additional amount occasionally as it works out.

Bright Dip for Iron.—Work that has been pickled in the ordinary way to remove sand and scale, and then dried, usually has a dull-black appearance. If the work is to be polished, the black will be removed and the colour restored in the polishing process; but if it is to be plated, or if it is to be left with parts of iron showing, the work should be run through the bright dip. This will bring it out white, improving the appearance and tending to make it take on a white deposit if it is to be nickelled. This dip is composed of :—

Hydrofluoric acid, 24 oz. Nitric acid, 10 oz. Metallic zinc, 2 oz. Water, 2 gals.

Work that is to be dipped should be strung on copper wire, and swirled around in the solution for a few seconds, rinsed in cold and then very hot water, and dried in sawdust. Articles should not be allowed to stay in the dip any time, as they would be spoiled and the solution ruined.

Satin-finish Dips.—Brass work requiring a satin finish may be dipped for a few seconds into a mixture consisting of :—

(1) Hydrofluoric acid, 1 part; Water, 3 parts;

then dried and run through the bright dip (4) to give it a lustre. If not satined enough the operation may be repeated.

(2) Hydrofluoric acid, 2 parts; Nitric acid, 1 part; Muriatic acid, ½ part; Water, 5 parts. After which the work may be rinsed, dried, and run through the bright dip (4) if necessary.

(3) Hydrofluoric acid, 2 parts; Nitric acid, 1 part; Water, 10 parts.

The following is a *bright dip* for copper, brass, bronze, or German silver :—

(4) Hydrofluoric acid, 4 quarts; Nitric acid, 3 quarts; Common salt, small handful.

Protection of Copper Castings.

The best method for protecting copper castings from oxidation in air, resulting in a coating of verdigris, is for the casting to be done under hot water, with the metal at a very high temperature. This method, largely employed in Japan, forms a coating of red cuprous oxide, which has been known to give protection for upwards of thirty years.

Die-Casting.

Contributed by A. H. Mundey, Assoc.Inst.C.E., F.C.S., M.Inst.Met., of Fry's Metal Foundries Ltd.

Die-castings have been defined as castings produced by pumping metal into metallic dies at a pressure higher than that of the atmosphere. This distinguishes them from the class of castings made by the permanent mould process into which the metal is simply poured, also sometimes referred to as die-castings and on other occasions as chill castings. There is, however, a tendency now to make the phrase 'die-casting' embrace both the methods, and to distinguish the sections as 'gravity die-castings' and 'pressure die-casting.'

The equipment for die-casting includes a melting pot (usually of cast iron), gas-heated, placed near the die-casting machine, for supplying the molten metal to the reservoirs of the caster.

The casting machines are of two general classes, those in which the metal is forced into the die or mould by the action of a plunger or pump, and the other in which compressed air is used for this purpose.

The reservoir attached to the machine is heated by gas, the pump being in direct contact with it; the plunger is actuated, by means of a long lever, by the operator, the metal being forced from the pump chamber through a suitable nozzle into the dies. The moulds are attached to a hinged plate which swings away from the reservoir and pump nozzle, after each cast, to allow the workmen to remove the tang and clean the metal passages.

The swinging plate is securely gripped to the reservoir at the moment of casting.

The mould is held to the swinging plate by means of a toggle joint, and varies in form and design according to the particular castings; it is always at least a two-part mould, but usually is also fitted with elaborate cores and drawbacks and mechanism for working them, which make the production of complex castings possible.

The dies are made in mild steel, alloy steel, and occasionally in cast iron, according to the alloy and character of the work in hand. Sometimes the dies are heated, for other work they are required to be water-cooled, so that no hard and fast line can be set in this respect.

The compressed-air type of die-casting machine consists of an air-tight cast-iron chamber for the metal, suitably heated to keep the metal at the desired temperature. This chamber is connected with the die by one opening, and with the compressed-air line, by another. In the latter opening a valve is fitted with a lever for the sudden release of the air into the metal chamber. This valve also permits of a gradual decrease of the pressure on the metal after it has filled the die. This type of machine may be used on metals cast by the plunger type, but is especially suitable for metals that cannot be cast in the plunger type of machine on account of their high melting-point or corrosive action on the cast-iron plunger.

A die-casting die consists essentially of two parts which are brought together and maintained in perfect register by means of the usual dowel pins.

Internal threads are produced by screwed cores and external ones by removable screwed collars, whilst the holes which are usually drilled in machine-made fittings are in these cases formed by means of retreating cores; the latter may be of almost any shape.

Small cores are operated by levers, large cores by a rack and pinion; they are always locked whilst the casting operation is proceeding. A vital consideration is the proper venting of the die; the position and form of the vents can only be determined by experiment.

Great accuracy is obtainable; it is quite possible to produce castings to a limit of 0·001 inch.

Alloys used for Die Castings.

The alloys generally used are of considerable variation, according to the special purpose and circumstances those of the white-brass or zinc-base group are usually approximately:

86 per cent. zinc.; 7 to 10 per cent. tin; 4 to 7 per cent. copper; with 0·5 to 1·0 per cent. aluminium.

Increased tin gives greater ductility, whilst increased copper renders the alloy harder.

The tin-base alloys are (*a*) bearing alloys of all the usual grades of white anti-friction metal, and (*b*) alloys specially designed to withstand the corrosive effect of chemicals in food-stuffs, certain gases, and even acids.

An alloy which is largely employed is :

90 per cent. tin ; 4 per cent. copper ; 6 per cent. antimony.

Of the aluminium group the most commonly used alloy is that known as No. 12, consisting of :

92 per cent. aluminium ; 8 per cent. copper.

Sometimes a small quantity of magnesium is added and also frequently from 1 to 3 per cent. of nickel.

The finish or skin of the casting is smooth and in a large measure satisfactory, but polishing, plating, and bronzing are frequently employed, for protective as well as decorative purposes.

Shrinkage is an important consideration ; this varies greatly with the alloys used. Approximate allowances are :

White brass or zinc base alloys . . .	0·0035
Lead base alloys	0·002
Aluminium alloys	0·007

The alloys generally used for die-castings are of relatively low melting-point and are of such a constitution that they have a period of plasticity during the process of solidification. This adds much to the chance of the production of sound castings.

Temperature of working is an important factor ; if too high, splashing results, with production of long fins, oxidation, and discomfort in working. Too low temperature produces bad finish with little folds and creases on the surface, due to premature solidification.

The metals known as yellow metals—that is, high copper alloys—have hitherto been cast almost exclusively by the gravity process. In these cases great accuracy is not obtainable for long runs, owing to the wear of the dies at the high temperatures employed.

A great advance has taken place, however, quite recently in the introduction of several processes for the production of yellow metal die-castings of very high finish, having high mechanical properties, by pressure machines. Fry's Metal Foundries, Ltd., have secured the Empire rights of a process which uses the metal to be cast in a plastic or semi-fluid condition. The machine employed is known as the ' Polak,' and operates by hydro-pneumatic pressure.

The yellow metal alloys usually employed for gravity castings are: copper 90 to 95 per cent., aluminium 10 to 5 per cent. ; also copper 60 to 65 per cent., zinc 40 to 35 per cent. For pressure work the series of alloys of the latter class are mostly employed.

Mechanical Treatment of Metals and Alloys.

Method of Treatment.	Details of Method to be avoided.	Consequences of Details of Method of Work.
Hot working . .	1. Excess 'reduction' or rate of 'reduction.'	Cracking of metal.
	2. Deficient 'reduction' or rate of 'reduction.'	Coarse, weak metal.
	3. Excess temperature at commencement.	Weak, brittle metal and formation of fissures therein.
	4. Deficient temperature at conclusion.	Internal strain and consequent hardening. Possible 'season cracking.'
	5. Retention of scale on metal during operations.	Rough and pitted surface and possible cracking.
Cold working .	1. Excess 'reduction' or rate of 'reduction,' without annealing.	Surface cracking and hollow drawing. Strain-hardening.
	2 Deficient 'reduction' or rate of 'reduction.'	Insufficient hardening — where hardening is expected.
	3. Unequal 'reduction' . . .	'Season cracking' or cracking during annealing.

Heat Treatment of Metals.

Method of Treatment.	Details of Method to be avoided.	Consequences of Details of Method of Work.
Annealing	1. At too high a temperature	'Burning' and 'over-heating' in steel and brass. Brittleness and sponginess generally, owing to abnormal grain size.
	2. At too low a temperature	Insufficient structure change.
	3. For too long a period — at correct temperature.	Diffusion and aggregation of micro-constituents of metal or alloy.
	4. Careless charging in or firing of furnace.	Sudden access of heat may lead to cracking of cold metal.
	5. In an injurious atmosphere or in contact with injurious substances.	Copper is injured by reducing gases, steel by oxidising gases. Water and oil have injurious effects in many cases.
Quenching	1. From too high a temperature	Cracking, warping and brittleness.
	2. From too low a temperature	The object of the operation is defeated.
	3. Unequal	Warping.
Tempering	1. At too high a temperature	Removes the effects of quenching.
	2. At too low a temperature	Does not remove the effects of quenching sufficiently.
	3. Unequal	Lack of uniformity and consequent failure.

SECTION XL

PART II

WELDING AND CUTTING.

(Contributed by D. Richardson, Wh. Exh., A.M.I.Mech.E., Capt. R.A.F.)

OXY-ACETYLENE WELDING.

The term ' autogenous welding ' is a cumbersome and loose description for the process, which has become synonymous with oxy-acetylene or gas welding, although its real meaning, ' self-producing,' does not fully apply. The term was chosen to describe a process in which two sections of metal are melted together by means of a blowpipe in contrast with the then existing methods, in which a joint was made by the addition of a different metal, as in brazing. The term ' fusion ' is considered to be much more appropriate than ' autogenous,' and is applied to a weld worked in the fluid or vapour state.

The easy control and intensity of the oxy-acetylene flame, the low cost of operation, the relatively inexpensive equipment required, the range of metals which can be welded, and the adequate supplies of carbide of calcium, oxygen, etc., available, are factors which have led to its many-and varied applications.

The industrial development which has taken place can also be attributed to the increased efficiency of the welder and the efforts that have been made to reduce the art of welding to a more scientific basis. The uncertainty of the results, upon which opposition and criticism are usually based, can, in general, be traced to one or more of the following causes : (*a*) inefficiency of the welder ; (*b*) use of defective or unsatisfactory apparatus ; (*c*) use of defective or unsuitable filling materials ; (*d*) lack of proper supervision and maintenance of the generating plant and equipment ; (*e*) unsuitability of the material welded.

It is not difficult to eliminate these causes, and a well-trained welder using good apparatus, correct filling materials, etc., can produce welded joints on mild steel, cast iron, copper, brasses, bronzes, aluminium and aluminium alloys, lead, etc., with mechanical and physical properties approaching those of the base metal, and in which the strength and service of the joint are absolutely reliable.

Equipment.

The apparatus required for an oxy-acetylene installation depends upon several factors, such as (*a*) the class of work to be welded; (*b*) whether a portable or stationary installation meets the case ; (*c*) whether production or repair work, or both, are possible applications ; (*d*) the facilities for installing equipment and for handling the work in prospect. In general, the apparatus and accessories will comprise a generator for generating the acetylene gas, which may be a fixed or portable plant—the most portable type of plant uses compressed or dissolved acetylene in portable cylinders instead of a generator ; chemical and mechanical purifying apparatus, when the gas is obtained from a generator ; oxygen apparatus for the production of oxygen, or oxygen in cylinders ; oxygen regulators for lowering and regulating the pressure of the gas after it leaves the cylinder, to the pressure required for the blowpipe, and, in the case of dissolved acetylene, an acetylene regulator for the same purpose ; hydraulic safety valve or other safety device for dealing with explosive mixtures of oxygen and acetylene or air and acetylene ; welding and cutting blowpipes of various capacities ; accessories, such as flexible tubing, goggles, welding benches, blowpipe support, preheating devices, tools, jigs, fluxes and filling materials, carbon paste and blocks, fire protection, protective equipment for the operator, etc., etc.

Fig. 1 shows in diagrammatic form an elevation and plan of the general layout of an acetylene welding and cutting installation. The letters refer to the same details in both views.

The acetylene generator, shown at A, is usually automatic—that is, the generation of gas is controlled entirely by the gasholder regulating the water supply or the carbide supply; B is

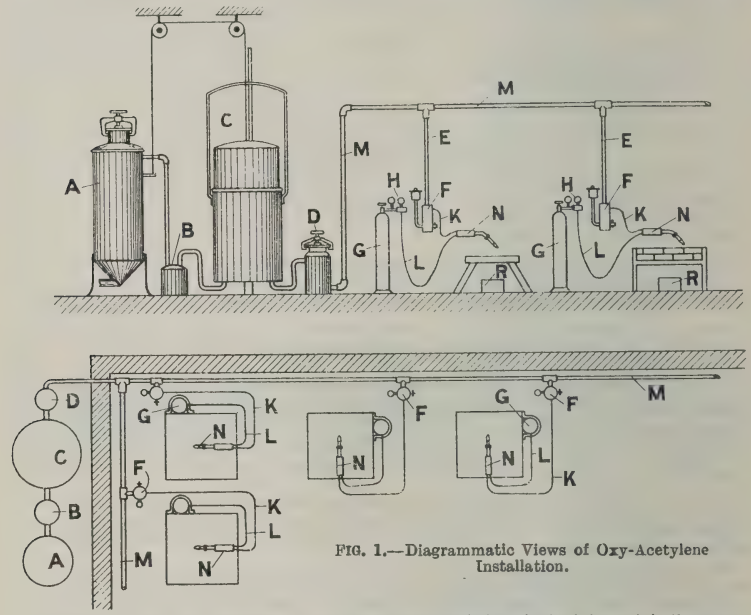

FIG. 1.—Diagrammatic Views of Oxy-Acetylene Installation.

a condenser, washer, and water-seal; C is a gasholder, consisting of a tank to contain the water-seal and a bell to store the gas; D is a purifying chamber and filter. The main piping, M, is connected to the purifying chamber and usually forms a complete circuit of the welding shop; branch pipes, E, are taken from the main for supplying acetylene to each welding station; F is the

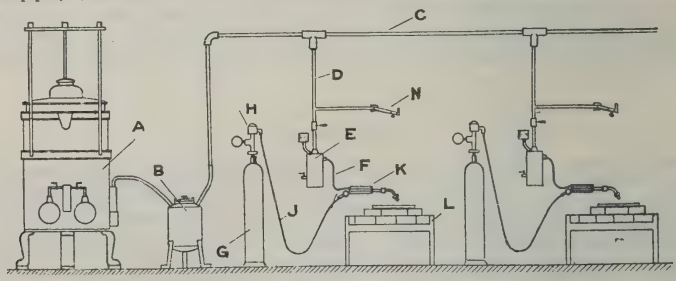

FIG. 2.—Diagrammatic View of Low-Pressure Oxy-Acetylene Installation.

hydraulic safety valve or other safety device; a flexible tube, K, connects the hydraulic safety valve to the welding or cutting blowpipe, N; G is the oxygen cylinder, on to which is screwed the oxygen regulator H; a flexible tube, L, connects the oxygen supply to the blowpipe N; two common types of welding benches, with blowpipe cooling tanks R, are shown.

For comparatively small installations, the generator, condenser, washer, water-seal, and gas-holder form a single piece of apparatus, as shown at A in fig. 2. The diagram shows at N a pilot light bracket attached to the branch tube D. An acetylene jet burner consuming about 5 litres of acetylene per hour, screwed into the bracket, forms an efficient and economical method of lighting the blowpipe. The burner should be at least 18 inches from the hydraulic safety valve and not more than 6 ft. above floor level. If arrangements are not made for an acetylene or coal-gas blowpipe lighting circuit a friction lighter should be used, not matches.

An installation of the type described is known as a low-pressure installation, to distinguish it from the type in which the acetylene is obtained from cylinders, known as the high-pressure system.

Fig. 3 shows the equipment for the high-pressure system. After passing through suitable acetylene and oxygen regulators the gases are conveyed to the blowpipe by means of flexible tubes.

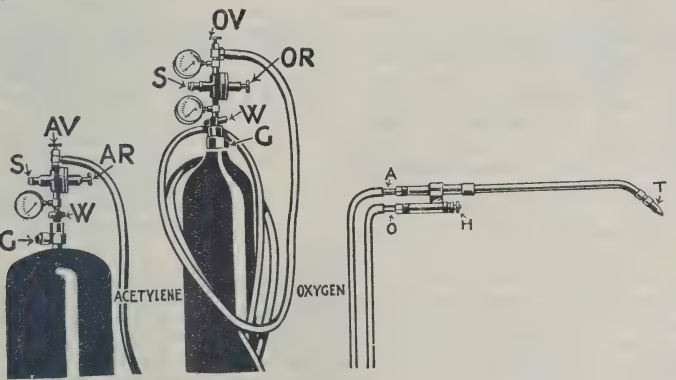

FIG. 3.—High Pressure or Dissolved Acetylene Installation.

OXYGEN SUPPLY.

The oxygen may be obtained in cylinders or may be produced on the premises. There are three methods of production, namely :—(1) chemical processes ; (2) the electrolytic process ; (3) the liquid air process. The older chemical processes are practically obsolete as regards oxygen for welding and cutting. Modern chemical processes are represented by the Oxygenite, Oxylithe, and Epurite processes. The main objections to chemical processes, which are now seldom used in welding and cutting processes, are the cost and impurity of the gas. The effect of impure oxygen in welding is to retard the welding operation, and thus increase the cost, and a tendency to produce defective welds. In cutting operations the purity of the oxygen is a most important factor, and tests have shown, for example, that with oxygen of 91 per cent. purity the cutting speed is halved when compared with oxygen of 98 per cent. purity. Simple and cheap apparatus is available for rapidly and accurately testing the purity of the gas.

The electrolytic and liquid-air processes may be used for producing oxygen on the premises. The gas can then be charged into cylinders or piped into the welding shop from large receivers into which it has been compressed, or it may be piped direct from the oxygen-producing plant. For information on ' Industrial Oxygen ' reference should be made to a paper read by T. Campbell Finlayson on the subject before the Institution of Chemical Engineers, in June 1923, and the Report of the Oxygen Research Committee, Department of Scientific and Industrial Research, Sept. 1923.

The problem of distributing oxygen in a liquid state instead of by the existing method of distributing the gas in steel cylinders at 120 to 150 atmospheres pressure is, at present, receiving considerable attention. Demonstrations showing the advantages of this system were given at the Annual Meeting of the German Acetylene Association. A liquid oxygen plant for oxy-acetylene welding has recently been installed at Middlesborough.

Oxygen produced by the electrolytic or liquid air processes has a purity of the order 99 per cent. Unless the consumption is very large the first cost of an oxygen installation is comparatively high, and the majority of users obtain the gas in cylinders from the manufacturers. The cylinders supplied by the manufacturers for welding and cutting usually contain 100 cu. ft. of gas at a pressure of 1,800 lbs. per sq. in. (120 atmospheres). The Gas Cylinders Research Committee of the Department of Scientific and Industrial Research have made a series of recommendations for ordinary commercial cylinders used for the storage and transport of gases including oxygen,

and are at present engaged on the standardisation of the fittings of gas cylinders.* They have also issued a Second Report dealing with the periodical heat-treatment of gas cylinders †; a Third Report dealing with alloy steel light cylinders ‡; and a Fourth Report, which completes the work for which the Committee was appointed, on cylinders for liquefiable gases.§ The Oxygen Research Committe have issued a Report mainly dealing with the storage and transport of liquefied gases, but also including a summary of the recommendations relating to compressed oxygen.‖ The British Engineering Standards Association have also formed a committee with a view to standardising cylinder valves and fittings.¶

In handling oxygen cylinders care must be taken against leakages, and particular care must be exercised not to oil or grease any part of the oxygen apparatus or supply line. Dust and moisture should be expelled by opening the cylinder valve before the cylinder is put into use. Repairs to cylinder valves should not be attempted by the user, and full cylinders should be handled carefully. All oxygen cylinders are fitted with valves having right-hand connections, and are generally painted black. No attempt should be made to transfer oxygen from one cylinder to another by rigging up some form of communicating tube. In the majority of cases a separate cylinder is used for each welding station or blowpipe in use. The arrangement of manifolding oxygen cylinders is being increasingly used as the handling of single cylinders, and wear and tear on the pressure regulators, is largely obviated. Oxygen manifolds should be able to withstand a pressure of at least 3,000 lbs. per sq. in., and each cylinder connection should be equipped with a high-pressure shut-off valve. It is extremely advisable that the necessary manifolds be purchased from a responsible manufacturer or made to specification. A cylinder valve should never be opened suddenly when the oxygen regulator is attached. In the event of the oxygen supply being restricted owing to the freezing of moisture in the cylinder valve, hot water only should be used to put it right. Leakages can be discovered by the hissing noise produced by the escaping oxygen, by the use of soap-suds spread over likely places, or by closing the valves on the blowpipe, cylinder, and regulator, and noting how long the pressure holds up on the gauges. Cylinders should be placed where they cannot be easily knocked over, and never near sources of heat. Spare cylinders should be safely and properly stored, care being taken not to store them near radiators, oil, grease, or combustible materials.

For estimating welding costs, the following table will be found useful. The table gives the number of cubic feet of oxygen remaining in a 100 cu. ft. cylinder corresponding to various readings of the high-pressure gauge on the oxygen regulator. The amount of oxygen indicated by the gauge reading is more or less approximate, as it depends upon the temperature of the oxygen. For practical work the deviations can be ignored, and would not affect the usefulness of the table. In general, the volume of oxygen in a cylinder is nearly proportional to its pressure, and thus, in the absence of the table, the volume of gas remaining in a cylinder can be determined by observing the gauge reading. A regulator provided with a pressure gauge which serves the double purpose of registering the pressure of the gas in the cylinder, and indicating at any period the quantity of gas in the cylinder, can be used.

Gauge Pressure in Atmospheres.	Cubic Feet of Oxygen in Cylinder.	Gauge Pressure in Atmospheres.	Cubic Feet of Oxygen in Cylinder.
10	8·3	70	58·4
20	16·7	80	66·7
30	25·0	90	75·0
40	33·4	100	83·4
50	41·7	110	91·7
60	50·0	120	100·0

At atmospheric pressure and temperature oxygen is rated at 12·08 cu. ft. per pound.

Oxygen is supplied to the trade at prices which vary according to the size of the cylinder, quantity purchased, and other conditions. Cylinders are loaned, or may be purchased outright. Demurrage charges are made on hired cylinders when retained above a certain period. The cylinder valve should always be closed when the cylinder is not in use and when returned for re-filling. Empty cylinders should be handled with the same care as for full cylinders. The proper care of cylinders and valves and their prompt return to the filling station are important factors in obtaining cheap oxygen. Oxygen cylinders are conveyed by the railway companies under strict regulations and conditions.

B.O.C. SERVICE
for all Welding Processes

Oxy-Acetylene · Electric Arc and Electric Resistance

ENGINEERS and manufacturers are invited to make use of the Company in any matter relating to welding. A staff of experts and demonstrators in each of the three main systems is always available to discuss problems and to show what can be done under practical conditions. Speed of work, strength and economy are the objects of all welding processes. Their adoption is daily increasing in all sorts of manufacturing and repair work. For the fullest information and enthusiastic help, write or telephone to the Company's Head Office, or to the nearest Branch.

The BRITISH OXYGEN Co LTD
Inc. ALLEN-LIVERSIDGE Ltd.

Head Office and Engineering Works:
ANGEL ROAD, EDMONTON, N.18

Offices & Works: Barrow-in-Furness, Belfast, Birkenhead, Birmingham, Bristol, Cardiff, Coventry, Crewe, Derby, Dundee, Erith, Glasgow, Hull, Jarrow, Leeds, Leith, Liverpool, London (N.W. & S.E.), Manchester, Newcastle-on-Tyne, Plymouth, Sheffield, Southampton, Stockton-on-Tees, Swansea, Witham, Wolverhampton: and in Australia, India and South Africa.

B.O.C. EQUIPMENT
FOR WELDING, LIGHTING AND METAL-CUTTING

INCLUDES:

OXY-ACETYLENE WELDING AND METAL-CUTTING

Oxygen, Dissolved Acetylene, Automatic Oxygen Cutting Machines, Acetylene Generating Plant, Blowpipes, Regulators, Fluxes, Wires, Tubing, Gloves, Goggles, Welding Tables, Trolleys, Carbide of Calcium, and all Accessories.

ELECTRIC WELDING

Electric Arc Welding Plant, Electric Resistance Welding Machines (Spot, Butt and Seam), Electric Rivet Heaters, Flux-coated and Bare Wire Electrodes, Electrode-holders, Masks and all Accessories.

PORTABLE LIGHTING

Alda-Lights (Dissolved Acetylene Flare Lights), Imperial Lights, Portable Lamps for all purposes, Searchlights, Motor Vehicle Lighting Equipment, Carbide of Calcium.

F. 2763

Acetylene Supply.

The acetylene may be obtained compressed in cylinders filled with a porous material, the pores of which hold a film of acetone in suspension, it is then known as dissolved or compressed acetylene, or may be generated on the premises. The precautions in handling acetylene cylinders are much the same as for oxygen cylinders. The gas should not be drawn off at too high a rate—in other words, the greater the demand the larger the cylinder. An investigation has been made to determine the percentage of acetone vapour in dissolved acetylene at varying temperatures and pressures. The figures show that the output of the flame diminishes by 1·8 per cent. for 1 per cent. of acetone vapour in the flame. The temperature of the cylinder should be kept low and the cylinder pressure should not fall too low in order to keep the percentage of acetone vapour low. For heavy continuous work two or more cylinders should be manifolded together by means of special adaptors supplied by the manufacturers. For general work cylinders containing 60 to 275 cu. ft. of gas are advisable. For light work such as thin sheet metal, lead burning, etc., small cylinders can be used with advantage. All acetylene cylinders used for oxy-acetylene welding are provided with valves screwed with left-hand threads, and are painted a dark reddish colour. Cylinders for welding and cutting can be hired or purchased. Always close the valves of empty cylinders. Stocks of oxygen and acetylene cylinders, whether full or empty, should not be stored in the same place unless there is a fire-resisting partition between them. Cylinders should be kept far enough away from the actual welding or cutting operation so that sparks or flame will not reach them. Acetylene should not be supplied from a battery of cylinders to a system of shop piping without consulting the suppliers of equipment.

Dissolved Acetylene Cylinders.

(British Oxygen Co., Ltd.)

40	28	6¼	2 0
60	70	8⅝	2 1
120	120	8⅝	3 4½
200	168	10	4 0

Before the gas is compressed into cylinders it is first purified and dried by several processes, and then compressed into solid drawn seamless steel cylinders.

The acetylene and oxygen being under high pressure, a perfectly uniform mixture of both gases can be maintained in the blowpipe and the pressure varied according to requirements. The elimination of the injector device, necessary in low-pressure blowpipes, and the hydraulic safety valve are advantages claimed for dissolved acetylene. Dissolved acetylene can be used with any type of oxy-acetylene blowpipe, but it should be recognised that the device for dealing with back-fires and flash-backs does not, as a rule, form part of the details of low-pressure blowpipes.

The amount of acetylene in a cylinder cannot be determined, as in the case of oxygen, from the pressure gauge reading. The only accurate method of calculating the gas used from, or left in, a cylinder is by weighing before and after use. The empty and full weights are shown on a label fixed to each cylinder after charging. For calculating the volume of acetylene used the following are the equivalents:

1·1 oz. of acetylene = 1 cu. ft. (approx.)
1 lb. ,, ,, = 14·5 cu. ft. ,,

By means of an acetylene generator acetylene is produced by the interaction of calcium carbide and water. There are three general types of acetylene generators which may be classed under the heads of water to carbide type, carbide to water type, and the dipping or displacement type. They can also be classified as low-pressure and pressure generators. Briefly, low-pressure generators deliver acetylene to the blowpipe at a pressure of about 8 ins. water pressure (0·036 lb. per sq. in.), whilst pressure generators deliver the gas up to a maximum fixed by the Home Office at 250 ins. water pressure (9 lbs. per sq. in.). The latter are not in general use.

The design and layout of a generating plant must be such that the acetylene reaches the blowpipe in a good condition, in sufficient quantity and at sufficient pressure, otherwise the welds may be porous, brittle, and burnt. The acetylene generator should be of good and solid

construction, and the gasholder capable of storing all gas generated under working conditions or after stoppage of work. There should be no signs of polymerisation or overheating of the gas even when working at the maximum delivery. The cross-section of tubes, pipes, and passages through valves should be such that the gas flows normally at the maximum delivery without loss of pressure. The pressure of gas should be as high as possible, and at least equal to 6 ins. of water pressure in the case of small plants, and 8 to 10 ins. in larger plants. The pressure should remain practically constant during working and not vary more than $\frac{1}{2}$ in. water pressure. The charging and cleaning of the plant should not result in any appreciable waste of gas, and be made without introducing sufficient air to interfere with the proper working of the blowpipe. The generator should comply with the Regulations of the British Acetylene and Welding Association. The size of carbide suitable for the type of generator should be used. For commercial purposes carbide is broken and packed in the following sizes: 80/120, 50/80, 25/50, 15/25, 7/15, 4/7, 2/4, and 1/2 millimetres. The figures refer to the approximate mean thickness of a lump in millimetres. The 50/80 size is in general use for welding and cutting generators. The choice of carbide-to-water, water-to-carbide, etc., generating plants depend on several factors, such as location, class of work, etc.

The Carbic system of generation is based upon the use of a carbic cake, which consists of specially prepared and treated carbide compressed into cylindrical cakes. It is claimed that the process renders every particle of carbide impervious to moisture, so that generation can only take place while water is in actual contact with the cake. Freedom from danger in handling, and from after-generation, convenience in handling, elimination of waste, and purity of gas are factors which have led to the success of this system.

Overloading of the plant is a common cause of defective welds. In carbide-to-water generators an allowance of not more than 1 cu. ft. of acetylene per hour for each pound of carbide in the rated charge is recommended. In the case of water-to-carbide generators the maximum rate of gas consumption should be half this value. In well-designed generators the yield of acetylene gas from the generator will be 85 to 90 per cent. of the carbide yield. Practically, for every 10 lbs. of carbide used in the generator a yield of 40 cu. ft. of gas at the blowpipe can be assumed. The proper care, cleaning, charging, and maintenance of generators is of first importance if reliable welds are required. Leakages of acetylene should be traced by means of soap-suds and never with naked lights.

The acetylene generating plant should be installed in a well-ventilated shed or building, or in a lean-to having no direct communication with a workshop or adjacent building, and no unauthorised person should be allowed to enter the building or enclosure. Where artificial light is required in a generator house or near a generator, electric incandescent bulbs, encased in outer gas-tight globes, should be used. A conspicuous notice prohibiting lights or smoking should be exhibited on the outside of the generator house. Generators should be cleaned and charged in daylight. Electric switches, fuses, etc., should be placed outside a generator house, or they should be so constructed that risks due to sparking or fusing are avoided. To comply with existing regulations, a licence under the Petroleum Acts must be obtained from the local authority for the storage of carbide. A sliding scale of licence fees, varying from 5*s.* to £5, according to the quantity stored, has been fixed, and severe penalties for contravening any condition printed or endorsed on the licence by the local authority are included. The London County Council have issued a circular setting forth the conditions which acetylene apparatus should fulfil before being approved for use on licensed premises.* A raised platform in the generator house should be provided for the storage of carbide. Drums containing carbide should not be placed in the welding shop or near a flame. Care must be exercised in opening drums to avoid striking sparks; a proper drum opener should be provided for this purpose. When the contents of an opened drum are not entirely used in charging the generator, the remainder should be transferred to a storage bin which can be sealed.

All users and prospective users of oxy-acetylene equipment should consult the memorandums issued by the Factory Department of the Home Office† and the Board of Trade.‡

Purification of Acetylene.

The chief impurities found in acetylene gas are (*a*) those which affect the quality of the weld, such as sulphur, phosphorus, silicon, finely subdivided lime; and (*b*) those which affect the cost of the weld, such as hydrogen and hydrogen compounds, nitrogen and nitrogen compounds, and water vapour. An efficient chemical purifer must be provided capable of removing sulphur and phosphorus compounds, the acetylene must pass through an efficient water-scrubber to remove or partially remove the impurities soluble in water and, finally, the gas should be filtered to remove solid impurities not eliminated by washing or chemical purification. A first-class purifying material will generally remove chemical impurities, moisture, and lime dust which are a common cause of defective welds.

Purification of the gas must be efficient, and the care and maintenance of the purifying chamber is very important. The cross-sectional area of the purifier should be ample, and the depth of purifying material should not exceed that specified by the makers, otherwise loss of

* 'Carbide of Calcium,' L.C.C. Public Control Department (Circular 80).
† Dangers from the use of acetylene gas and in oxy-acetylene welding in factories (Form 1704).
‡ Instructions to Surveyors. Repairs to Boilers (Circular 1596).

pressure and overheating of the gas will take place. The quality of the gas can be simply and quickly tested by the use of a white absorbent paper, saturated with a 10 per cent. solution of silver nitrate, exposed to the gas. Should the paper turn black after a few seconds' exposure, the gas is unsuitable for welding purposes.

Among the best known purifying materials are Heratol, Catalysol, Klenzol, and Suder. The three last are distinguished by their regenerative properties—that is, they recover their activity by simple exposure to the air, and thus can be used over and over again. In purifying acetylene the cost should be based on the volume of gas purified and not on the first cost of the material.

Preservation of Acetylene Apparatus.

The question of preventing the corrosion or deterioration of the material used in the manufacture of acetylene generators, purifying vessels, and other parts of the generating plant is important in view of the fact that according to the efficiency of the coating the life of the plant may be a question of months or years.

There are five cases to be considered, namely: (*a*) preservation of the external parts of the apparatus; (*b*) preservation of the immersed parts; (*c*) preservation of parts in contact with moist and impure gas; (*d*) preservation of the interior of purifying vessels; and (*e*) preservation of carbide containers. With regard to (*a*), good ironwork paints give good results when applied well to properly prepared surfaces. At least two coats should be applied. If the apparatus is exposed avoid paints used for woodwork, plaster, etc. For (*b*) it is necessary to use a waterproof paint which will resist the prolonged action of water. The best results are obtained when the base consists of tar and graphite. For (*c*) the paints used for immersed parts of acetylene apparatus give the best results, but the work must be done with great care. For (*d*) the majority of industrial preservative paints give satisfactory results, except those containing a zinc or similar base. Several coats are necessary, and great care is required in applying the coats on to well-prepared surfaces. For (*e*) tests have shown that no paint or coating will satisfactorily resist the action of the lime residue at the temperatures usually present, and that the lime residue appears to have a preservative action on the parts with which it is in contact. It is therefore unnecessary to protect these parts.

Oxygen and Acetylene Regulators.

Regulators in common use to reduce the pressure of gases are of the diaphragm type, and may be roughly divided into two classes—first, where the pressure of the gas closes the inlet, and, second, where the inlet is closed by a spring. They are designed to automatically deliver gas to the blowpipe at any uniform pressure to which the regulator is set. They should be designed for working over a wide range of pressures, and should be sensitive even at low pressures. Oxygen regulators are usually equipped with two gauges, a high-pressure gauge, which shows the pressure of gas in the cylinder, and in some types the quantity of gas in the cylinder, and a low-pressure gauge. Pressure gauges should be provided with a check to prevent a sudden inrush of gas. For successful welding the regulator should be provided with a low-pressure gauge, giving the pressure at which the gas is delivered to the blowpipe. The range of the low-pressure gauge should not be too great, and a maximum reading of 75 lbs. per sq. in. will be sufficient for the majority of welding and cutting operations. Regulators must be kept in good order, otherwise defective welds are inevitable. Regulators intended for use when welding should not be used when cutting unless the work is within the range of the regulator. It is dangerous to use oil, grease, or any organic material for lubrication. If it becomes necessary to lubricate the pressure-regulating screw, or to repack a needle valve, a little glycerine should be used. The pressure-adjusting screw should always be released after ceasing work and before changing from one cylinder to another. Creeping regulators or regulators with leaky valve seats should be overhauled, because they are likely to become dangerous and uneconomical. The gradual increase of pressure when the blowpipe is shut off indicates a creeping regulator. Devices in the form of electric heaters, which prevent freezing of regulators and thus interference with the supply of oxygen, are now available and are compact and convenient where electric current is available. They are interposed between the cylinder and the regulator. Regulator gauges should be tested at regular intervals but never tested with an oil-testing pump.

Acetylene regulators are usually painted red and have a left-hand screw thread corresponding to that on the standard valves of acetylene cylinders. Regulators for oxygen are usually painted black and have a right-hand screw thread. Any possible confusion is obviated by this distinction. Before connecting the oxygen regulator to the cylinder open the oxygen cylinder valve for an instant and then close it.

Cylinder valves should be opened very slowly so that pressure does not suddenly come on to the gauges or diaphragm. The proper working of regulators largely depends upon the care given them. They should not be left in places where dirt or dust may get into the interior and be deposited on the seat or inlet nozzle, and they should never be repaired by inexperienced workmen.

Hydraulic Safety Valves.

These are indispensable in low-pressure and medium-pressure installations, i.e. where the acetylene is generated on the premises. Their function is to provide a water-seal and to prevent explosive mixtures entering the acetylene piping or generating plant. The valve should be chosen so that the maximum supply of gas is obtained without burning the metal. Safety

devices based on mechanical principles, such as valves, etc., may more or less prevent the return of the flame, but are not infallible in preventing explosive mixtures forming in the generating plant.

Hydraulic safety valves should be charged and examined daily, and should be installed so as to facilitate filling to the proper level. The local authority responsible for issuing the carbide licence generally insists on the provision of a metal shield for the valve, to avoid accidents in the event of the valve being fractured. In general, the valve should be charged with water whilst the acetylene tap admitting gas to the valve is open. The design should be such that no water is carried over with the gas. An investigation has shown that the water vapour contained in the gas after passing through the hydraulic valve rises with the temperature, and can attain 7 per cent. when the gas is at 97° F. With 2·5 per cent. of water vapour, there is a reduction of over 8 per cent. in the speed of welding. No safety valve should have more than one outlet to which a blowpipe can be connected.

Pressure relief valves or safety valves used on pressure generators should be tested periodically; they do not replace the hydraulic safety valve, which is still required in a modified form.

Piping and Flexible Tubes.

The acetylene piping should be large enough to avoid loss of pressure. The size of piping should be dependent upon its length and the maximum supply of gas required. All piping should, when possible and convenient, be run overhead. When piping has to be run underground it should be placed in properly ventilated trenches. Piping and connections should be installed by workmen experienced in the installation of acetylene apparatus. Piping should be so arranged that any moisture will drain back to the generator, and where low points cannot be avoided these must be drained through drip cups closed with screw caps or plugs. No pet cocks should be used. A main gas cock should be arranged where it can be conveniently reached and near the point of entrance, so as to allow for shutting off the gas supply from any workshop. Gas cocks should be provided on the branch tube leading to the hydraulic valve so that a valve may be removed without discharging the line. All cocks, valves, unions, and joints should be full bore, and the installation should be thoroughly tested when the system is completed, and at regular intervals. It should not show a loss of pressure exceeding two inches of mercury within twelve hours when subjected to a pressure equal to a column of fifteen inches of mercury. Acetylene piping should be painted a distinctive colour. Galvanised iron pipe with welded or threaded connections should be used for piping acetylene. The pipes should be of uniform diameter, and bends—the number of which should be as small as possible—should be used in preference to square elbows. Compressed oxygen should never be used for testing or cleaning acetylene piping. If compressed air is used for this purpose the acetylene plant should be disconnected.

The following table will serve as a guide in installing acetylene piping for welding purposes. Manufacturers of welding equipment will supply full particulars as to pipe sizes suitable for any particular layout.

Acetylene Main Piping.

Approximate Diameters of Service Piping. For working pressure of 6 *in. to* 10 *in. water column.*

Consumption of Acetylene per hour.	Length of Pipe.	Internal Diam. of Piping.
Cubic feet.	Feet.	Inches.
15	100	$\frac{1}{2}$
40	100	$\frac{3}{4}$
80	100	1
140	100	$1\frac{1}{4}$
225	100	$1\frac{1}{2}$
400	200	2
1000	200	3
2500	200	4

Ordinary black steel piping may be used for low-pressure oxygen, and extra heavy steel pipe for high-pressure lines. The suitability of steel piping for this purpose is being investigated, and some manufacturers recommend copper piping from the point of view of safety and convenience. It is advisable for prospective users of oxygen pipe lines, headers, and manifolds to purchase them from, and have them installed by, reliable manufacturers familiar with the correct shop practice with reference to their construction and installation. No oil or grease must be used for the connections; litharge and glycerine should be used. The diameter of oxygen piping will depend on the length of the lines. A $\frac{3}{4}$-in. pipe is suitable for supplying twenty welding stations, provided the length of the line is not more than 300 ft. and the maximum consumption is not more than 500 cu. ft. per hour.

The flexible tubes conveying the gases to the blowpipe should not be too long, too flexible, or too rigid. The strength should be such that for welding purposes the tube should withstand a pressure of 100 lbs. per sq. in. without bursting, swelling, or leaking, and for use in cutting operations it should withstand 300 lbs. per sq. in. Armoured or wired hose is not necessary or recommended for ordinary welding and cutting operations. Three-ply tubing with a core of pure rubber is satisfactory for ordinary work, and for welding and cutting in confined spaces fire-resisting hose should be used. Avoid greasing the ends of the tube to facilitate fixing to the blowpipe or other connectors; use water. No white lead, oil or grease, or other pipe-fitting compounds, should be used for making tight joints. Tube clips should be used in preference to wire, etc., for securing the tube firmly to the connectors.

Flexible tubing should be examined regularly, and defective tubing should never be used. Avoid tangling or kinking the hose, long lengths—about 10 ft. lengths are suitable for stationary equipment and 15 ft. for portable—dragging the hose along the floor, and exposing it where it is likely to get damaged. Special care should be taken to avoid the interchange of the oxygen and acetylene tubes when connecting up to the blowpipe. Both acetylene and oxygen tubing should be blown through occasionally, so that dirt and dust will not get carried into the blowpipe, and tubing should be examined and tested periodically.

Welding Blowpipes.

Welding blowpipes are classified in relation to the pressure of the acetylene. Low-pressure blowpipes are those fitted with an injector to aspirate the acetylene, which is supplied from a generator under a pressure of 6 to 12 ins. of water. Medium-pressure blowpipes, sometimes called positive pressure, use acetylene generated from a pressure generator at a pressure up to 9 lbs. per sq. in. An injector or partial injector forms part of the blowpipe. High-pressure blowpipes use the acetylene supplied from acetylene cylinders, and are designed to mix acetylene and oxygen in equal volumes. No injector is required, and a change of nozzle with a corresponding adjustment of pressures is all that is required when changing over from welding one thickness of material to another.

In the low-pressure system thorough mixing of the gases in the blowpipe is very necessary. To obtain this, well-designed blowpipes carefully adjusted to the oxygen pressure recommended by the maker, are essential. A typical low-pressure blowpipe working on the injector principle is shown in fig. 4.

The size or power of blowpipe which should be used depends upon the thickness to be welded. By power is meant the amount of acetylene consumed per hour. Too small a power produces the defects of adhesion, inclusion of oxide, overheating, and burning of the welds. Too large a power produces a molten bath which is much too large, holes, and adhesion in the lower part of the weld.

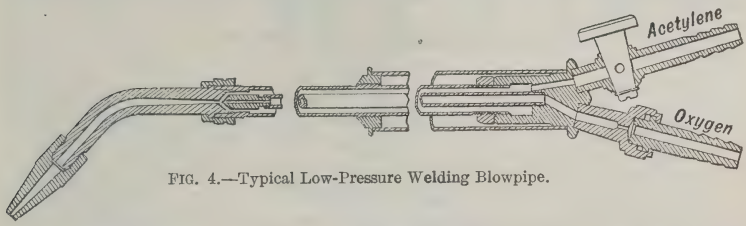

Fig. 4.—Typical Low-Pressure Welding Blowpipe.

The figure denoting the power of blowpipes is usually supplied by the maker, and is sometimes marked on the blowpipe. In welding materials other than wrought iron and steel the power of blowpipe to be used is dependent upon the material, its dimensions, and whether the job has been preheated; as a general rule the power of blowpipe for a given thickness of material is greater, as in melting, for example, cast iron, copper, or aluminium, more heat is required to melt a given weight of the metal, and, in addition, the high-temperature part of the flame is held farther from the molten metal.

All blowpipes should be carefully handled and treated as precision tools. The procedure to be followed in lighting and extinguishing the blowpipes varies with the design and type of blowpipe. The manufacturer's instructions should be closely followed. Lighting devices are convenient and safer than matches. A blowpipe should never be put down, unless a blowpipe stand is provided, until the gases are turned off, and should never be hung from regulators or other equipment. Gas economisers which serve the purpose of a stand and automatically cuts off the gases, except sufficient acetylene for a pilot jet, are valuable, especially in repetition work. Blowpipes in which the acetylene valve is entirely independent of a single valve which controls both gases, thus obviating the adjustment of the flame every time the blowpipe is lit, can be obtained. Carefully avoid the use of grease or oil, and never dismantle a blowpipe with a view to overhauling, as this may lead to irregular working after assembling. In the event of obstruction of the nozzle, a soft brass wire should be used for cleaning. Dust in the interior of the blowpipe can be

removed by blowing oxygen through from the nozzle end. Equipment should be inspected at frequent intervals by a competent operator, and only standard parts should be used in repairs to apparatus.

In the case of back-firing or flash-back due to overheating, the tip should be cooled in water, taking care to close the acetylene valve and to leave the oxygen valve slightly open. By back-fire is meant the momentary return of the flame into the blowpipe tip, which may relight immediately upon withdrawing the blowpipe away from the work or necessitate the reignition of the gases by means of a lighter. By flash-back is meant a sustained back-fire, the flame burning in the mixing chamber with a squealing sound accompanied by a smoky, sharp-pointed flame, necessitating the immediate cutting off of the gas supply, to prevent severe heating and possible destruction of the blowpipe head, and the subsequent cleaning to remove carbon deposits. If internal ignition occurs frequently the blowpipe should be sent for repair. An iron or steel wire should never be used for cleaning the nozzle.

Back-firing and flash-backs, which are a common cause of defective and expensive welds, may be due to one of the following causes:—

(*a*) Faulty design and manipulation of the blowpipe.
(*b*) Enlarging the nozzle orifice when removing obstructions.
(*c*) Working in confined spaces or with an accumulation of slag on the nozzle.
(*d*) Necessity for overhauling and internal cleaning.
(*e*) Restriction and fluctuation in the acetylene supply due to bad lay-out, exhausted purifier, etc.
(*f*) Defective hydraulic safety valves leading to air and moisture being carried with the gas.
(*g*) Defective oxygen regulators.
(*h*) Presence of solid matter in the gas either from the acetylene generator or inferior flexible tubing.

Oxy-Acetylene Flame Characteristics.

The combustion of acetylene in oxygen produces a flame which apparently consists of two parts —an inner cone, incandescent, clear, and well defined; and a non-luminous outer envelope which may be transparent or more or less opaque according to the purity of the acetylene. In a well-regulated and correctly designed blowpipe there is, between the inner white cone and outer envelope, a reducing zone which is distinctly visible when the acetylene is impure. The exact character of the flame will depend on the proportion of the oxygen and acetylene as they emerge from the nozzle. The oxygen and acetylene should mix in approximately equal proportions. Gas-ratio, or the ratio of the oxygen to the acetylene consumption, is an important factor in determining the quality and cost of welds. Varying proportions of the gases produce three characteristic types of flames, commonly known as carbonising, neutral or normal, and oxidising. These

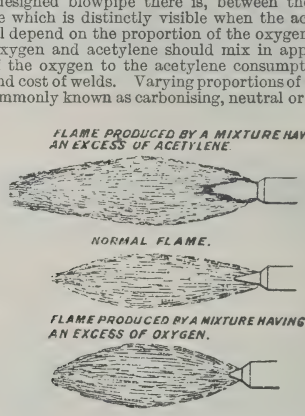

Fig. 5.—Flame Characteristics.

are shown in fig. 5. It is important that in practically all welding operations the flame should be neutral—that is, there should be no excess of oxygen or acetylene. Defective welds are produced with carbonising and oxidising flames. It is particularly important that there should be no excess of oxygen, which not only tends to produce weak welds, but also to blow the metal forward and produce adhesion. Regulation of the flame during important welding operations is essential, as very few blowpipes maintain a neutral flame under welding conditions, and further, the operator has a tendency to adjust the flame oxidising. It is advisable to adjust the flame whilst wearing dark glass goggles.

It is necessary to emphasise that the white cone of the flame should never be brought into contact with the molten metal, and that its distance from the molten metal depends, in general, upon the metal being welded and its thickness.

FERROX

WIRES *for* FINEST WELDS

MADE ONLY FOR WELDING

The raw material which forms the starting-point of FERROX manufacture is of at least as high quality as the best of other brands. EVERY COIL as it enters the factory is CHECKED BY ANALYSIS before release for treatment under the unique FERROX process, whereby the metal is purified, softened and impregnated with elements which impart to the welding process and the weld those qualities which have made FERROX WIRE stand for FINE WELDING. FEED RODS and FLUXES for welding of grey cast iron, aluminium and other non-ferrous metals and alloys.

Goggles and Protective Equipment.

For welding with acetylene it is necessary to protect the eyes with goggles fitted with suitable coloured glasses. There are a great many different kinds of special safety glasses on the market and many combinations of ordinary coloured glass are in common use. The eyes must be protected from injurious rays, the heat and glare from the work, and from particles of hot metal that fly up from the weld. To obtain the clearest definition or visibility with the least amount of glare, the selection of the colour tint in safety glasses should properly be decided by an expert; the depth of the tint may be determined best by the operator himself, owing to the individual difference which will permit one man to see clearly through a glass that would be too dark for another man. Amber, dark-amber, or dark-amber-green glasses give efficient protection. Glasses showing blue or violet tints should be avoided, except in certain combinations where they are used to obscure other colours. For the frames a tough heat-resisting material like vulcanised fibre is advantageous. Goggles should be light, comfortable, and well ventilated, and should be obtained from the manufacturer of welding supplies.

Welders employed on heavy work should be supplied with fireproof gauntlets and aprons, as a protection against radiated heat, and where welding is being performed in the interior of some structure or confined space all the outer clothing should be fireproof.

Filling Materials.

The necessity for employing the best materials for every welding operation cannot be too strongly emphasised. It is only by using the most suitable filling-in wires, rods, and fluxes, specially manufactured and controlled for each particular metal or alloy, that the most satisfactory work can be done.

Thin material is frequently welded by flanging, bringing the edges into contact and melting them together, but generally a filling material or ' welding rod ' is melted into the groove or crack.

Filling materials must, where possible, not only be of the correct chemical requirements to (*a*) replace loss in the molten zone, (*b*) counteract the tendency of the metal to oxidise, (*c*) assist in making the molten metal flow readily, and (*d*) to break down oxides when formed, but they should also act satisfactorily under the blowpipe. As a general rule, the welding wire or rod should have practically the same composition as the material to be welded.

The choice of the right size of welding wire or rod is important, and melting of both should take place in the molten bath and not in the flame. The following table gives the sizes of wire for ' forward ' welding sheet iron and steel. In the case of other metals the figures hold good, except for very thin material, when a size of not less than $\frac{1}{16}$ in. should be used.

Sizes of Welding Wire for Iron and Steel (' Forward ' Welding).

Thickness of Material. No.	Size of Welding Wire.		
	S.W.G.	Decimal Equivalent.	Nearest $\frac{1}{64}$.
20 B.G.	19	0·040	3
14 B.G.	14	0·081	5
10 B.G.			
8 B.G.	11	0·116	8
6 B.G.			
4 B.G.	8	0·160	10
3 B.G.	6 to 4	0·192	12
1 B.G.		to 0·232	15
1/0 B.G.	4 to 2	0·232	15
5/0 B.G.		0·276	18

The following table also gives the sizes of wire for ' backward ' welding; it should be pointed out that this method of welding is more reliable and economical than ' forward ' welding, and is rapidly displacing the latter for welding iron and steel of medium and heavy thicknesses.

SIZES OF WELDING WIRE FOR IRON AND STEEL ('BACKWARD' WELDING).

Thickness of Material.	Size of Welding Wire.		
	S.W.G.	Decimal Equivalent.	Nearest $\frac{1}{64}$.
Up to 6 B.G.	11	0·116	8
6 B.G. to 2 B.G.	8	0·160	10
1/0 B.G.	6	0·192	12
1/0 to 6/0 B.G.	4	0·232	15

Fluxes.

It is not always possible to include deoxidisers and special elements in the welding rod itself. By using a combination of chemicals in the form of a powder, liquid, or paste, known as a flux. the difficulties of producing sound and reliable welds are frequently overcome. A flux is used for (*a*) cleaning the parts to be welded; (*b*) eliminating and preventing the formation of oxide; (*c*) replacing elements burnt out by the flame; (*d*) facilitating the flow of the metal, and, when melted, (*e*) protecting the surface of the molten metal from the action of the flame and preventing blow-holes. The reducing zone of a well-regulated and well-manipulated flame protects, in a measure, the molten metal from oxidation. A flux is necessary in welding steel (except in cases where the steel welding wire contains deoxidising materials, as, for example, Ferrox), cast iron, copper, aluminium. etc.; for successful welding the proper flux should be used, and as the welding rod and flux are important factors in welding they should only be obtained from reliable manufacturers.

Preparation of the Work.

One of the first principles of sound welding is securing complete fusion and perfect union of the filling material and the edges of the parts to be welded. To ensure this, good preparation is necessary, which includes, as a rule, the cleaning of the edges and the welding wire, the bevelling or chamfering of the edges, the adjustment and maintenance of the parts in position, and allowance for expansion and contraction effects. In general, the preparation of the parts varies according to the thickness and nature of the metal and with the organisation and equipment of the workshop.

Cleaning the parts to be welded and the welding wire or rod is essential. Bevelling is necessary for materials $\frac{1}{8}$ in. and above in thickness. Bevelling ensures good penetration, increase in ductility and strength, economy, and reduction in the overheating effects. The angle of the bevel depends upon the thickness of material and whether 'forward' or 'backward' welding is used. All metals from $\frac{1}{8}$ in. up to $\frac{3}{8}$ in., and in some cases $\frac{1}{2}$ in., should be bevelled from one side only. Pieces exceeding $\frac{1}{2}$ in. may be bevelled from both sides. In forward welding the 'V' formed by the two bevelled plates should be about 90° for material exceeding $\frac{1}{4}$ in. in thickness, and 50° to 60° for material $\frac{1}{8}$ to $\frac{1}{4}$ in. In backward welding for material up to $\frac{1}{4}$ in. an angle of about 45°, and above $\frac{1}{4}$ in. an angle of 60°, can be used. The bevel should extend to the bottom of the plate, and thorough penetration and complete fusion should be obtained. In repair work preparation of the work is a very important feature and will save considerable time and keep the cost of welding low. Should it be necessary to re-weld a joint previously welded, it is essential that the weld metal be entirely removed, and on old work the same instruction applies, and corroded metal must be removed. In the case of aluminium repairs, for example, good judgment, as shown by the preparation, means success, and bad judgment a ruined casting.

Expansion and Contraction.

It is impossible to produce satisfactory work unless expansion and contraction effects are properly allowed for. Warpage and residual stresses, followed by failure, are the common result of welders failing to master this subject. The methods commonly employed are, in the case of thin sheets, tacking; in the case of heavier material and castings, setting the plates so as to form an angle, heating the entire work, partial heating, heating restraining members, breaking a member so that expansion and contraction can take place freely, bending or springing the material, etc.

If expansion can take place in all directions, it will give the welder no trouble, but he should operate so as to leave practically no residual stresses. If, however, welding takes place at a place that is confined by various parts or by the particular construction of a piece, it is necessary to give it due consideration.

The effects of contraction must be considered equally with those of expansion, as failures, cracks, etc., can often be traced to neglect of this property.

Preheating.

This may be partial or total, depending upon the work in hand, and is mainly employed with a view to (*a*) allowing for expansion and contraction, (*b*) decreasing the cost of welding, and (*c*) producing a more homogeneous joint. Preheating is usually carried out with the welding blowpipe, oil or gas burners, charcoal, or other suitable fuel. Where fuels such as charcoal are used for preheating, the combustion gases should, where possible, be carried away. In any case ventilation should be provided to avoid the harmful effects of the gases produced by combustion. The method used should be governed by the particular work in hand.

No general rules can be given for preheating temperatures, as the degree of heat necessary will, of course, depend upon the size and shape of the object to be welded. As a general rule, however, cast iron should be preheated to a dull red heat for small and simple castings, and to a blood-red heat for large or complex castings; aluminium and its alloys should be preheated very carefully, as too high a temperature will lead to the collapse or distortion of the article being welded.

Preheating machines burning paraffin and giving a flame of high calorific value, smokeless and transparent, give satisfactory results where portability and a powerful flame are required.

After-Treatment of Welds.

Improvement in the structure of welds with a consequent increase in strength and ductility is the result of proper after-treatment of welds. Thermal or mechanical treatment, or both, carried out in a correct manner is invariably beneficial, except in the case of defective welds.

Strength of Welds.

With proper equipment and suitable filling materials, the strength of a weld will depend mainly upon the care and skill of the operator. A good operator should be able to obtain welds 95 per cent. the strength of the original material on material of good weldability; for the average welder 85 per cent. should be taken as the lower limit of strength.

Recognition of Materials.

The identification of the metal, especially in repair work, is invariably indispensable. Once the metal or alloy is known the next step is to get familiar with all the facts relating to its weldability and, in case of doubt, proceed to the necessary tests for determining these. Some of the means by which the materials of the parts to be welded may be recognised are as follows: colouring, appearance of surface, contour, grinding spark test, chisel cut, fracture, blowpipe test.

Steel Welding.

The welding of wrought iron and mild steel is apparently simple; in reality it is somewhat difficult to produce strong and reliable welds. Oxidation and inclusions are the most serious defects, and must be reduced to a minimum. Welding wires containing a small percentage of vanadium or nickel are used with highly satisfactory results. To produce the minimum oxidation the blowpipe must be well designed and handled efficiently, and the parts to be welded must be thoroughly cleaned. Expansion and contraction must receive proper consideration. The use of a flux in the form of a powder has not proved satisfactory. It has been found that deoxidising materials in the form of a liquid gives excellent results. The product known as 'Suder' is specially prepared for use with a welding wire which does not contain deoxidising elements. At the high temperature of the flame it slags the oxide, keeps the surfaces clean, and prevents the inclusion of oxide. The weld can be carried out rapidly, thus reducing overheating effects. The liquid is applied by means of a brush to the edges of the plates and the welding wire previous to welding. The welding wire should be a material low in phosphorus and sulphur, and free from oxide. The use of ordinary iron or mild steel is unsatisfactory, and welding wire, such as 'Suder' or 'Ferrox,' made especially for the oxy-acetylene process, should be insisted upon. It will be found that economy is on the side of the controlled, but slightly more costly, and dependable product.

The following abstract from a specification for a welding wire for iron and mild steels is of interest and represents the American Welding Society's Specification for the welding wire for oxy-acetylene welding mild steel, structural work, plates, bars, low carbon steel forgings and castings. The surface of the wire is to be smooth, of uniform homogeneous structure, free from irregularities in surface hardness, segregation, oxides, pipe, seams, etc. Diameter shall not vary more than

+ 3 per cent. of the diameter specified. The chemical composition to be within the following limits :—

Carbon	not more than	0·06 per cent.
Silicon	,,	0·08 ,,
Manganese	,,	0·15 ,,
Sulphur	,,	0·04 ,,
Phosphorus	,,	0·04 ,,

The surface shall be smooth and free from scale, rust, oil, or grease. In the hands of an experienced welder the wire shall demonstrate good weldability, and shall flow smoothly and evenly without any unusual characteristics.

For welding mild steel and to produce a weld of greater strength but of lower ductility than that obtained with ordinary welding wire, the wire may contain 0·15 to 0·25 per cent. of carbon, 3·25 to 3·75 per cent. of nickel, and 0·5 to 0·8 per cent. of manganese.

A simple test to indicate the fitness of welding wire is made by laying the wire flat on a clean surface and applying a good neutral oxy-acetylene flame to the wire in such a manner as to heat it up for a distance of about 3 or 4 ins., playing the flame backwards and forwards until the wire is red and then slowly melting the wire, moving the flame so that the wire only melts halfway through its diameter. If the flame is withdrawn as soon as the metal begins to melt, the impurities can readily be seen being thrown off in the form of sparks, or a boiling action in the case of inferior metal ; and in some cases the metal will not flow together but ' runs away.' The metal from gas absorbing wires will, when cold, contain numerous spongy, volcano-like irregularities. In the case of clean metal free from impurities the wire will melt and flow evenly without any disturbing action.

The following table is useful when ordering welding wire :

Size. Inches	$\frac{1}{16}$	$\frac{3}{32}$	$\frac{1}{8}$	$\frac{5}{32}$	$\frac{3}{16}$	$\frac{1}{4}$	$\frac{5}{16}$	$\frac{3}{8}$
Lbs. per 100 ft. .	1·04	2·3	4·1	6·5	9·3	16·7	26	37·5
Ft. per 100 lbs. .	9,615	4,273	2,403	1,537	1,067	600	383	266

The flame must be carefully regulated and held so that the tip of the white cone is about $\frac{1}{8}$ in. from the surface of the molten metal.

A good practical rule in welding steel is that the hourly consumption of acetylene should be $4\frac{1}{4}$ to $5\frac{1}{2}$ cu. ft. (120 to 160 litres) for every $\frac{1}{16}$ in. in thickness.

The following useful table is based upon these figures, in which the approximate bore of the nozzle orifice is also included :—

POWER OF BLOWPIPE FOR IRON AND STEEL.

Thickness of Material in Inches.	Consumption of Acetylene per Hour.		Bore of Nozzle in $\frac{1}{64}$ inch.
	In Litres.	In Cubic Feet.	
22 gauge	60–80	$2\frac{1}{2}$–$2\frac{3}{4}$	2
$\frac{1}{16}$	120–160	$4\frac{1}{2}$–$5\frac{1}{2}$	3
$\frac{1}{8}$	240–320	$8\frac{1}{2}$–11	3 full
$\frac{3}{16}$	360–480	$12\frac{3}{4}$–$16\frac{1}{2}$	4
$\frac{1}{4}$	480–640	17–22	5
$\frac{3}{8}$	720–960	$25\frac{1}{2}$–33	6
$\frac{1}{2}$	960–1280	34–44	7
$\frac{5}{8}$	1200–1600	$42\frac{1}{2}$–55	8

The blowpipe must be given a motion which will cause the flame to describe a series of overlapping circles in the case of light and medium sheets, and oscillated in a series of overlapping semicircles in the case of heavy sections. This is known as ' forward ' welding. A variation of these movements has been introduced which gives more economical and better welds. The welding wire, in this case, follows the flame instead of preceding it, and the flame is directed towards the starting point instead of towards the finishing point. The blowpipe is given a slight gyratory motion, whilst the welding rod is given a more or less elliptical or longitudinal motion. This method of welding is known as ' backward ' welding. Subsequent thermal treatment, which may consist of annealing or normalising, according to the particular requirements, will improve the structure of steel welds and materially increase the strength and toughness of the weld. Hammering may be resorted to with good effect, provided the hammering is not too vigorous or done at too low a temperature.

The following table gives the speed at which the welding of mild steel plates can be done under average conditions :—

Thickness of Plate in Inches.	Speed of Welding.	
	Feet per Hour.	Feet per Hour for Average Day's Work.
$\frac{3}{64}$	30 to 33	23 to 26
$\frac{5}{64}$	20 „ 21	16 „ 20
$\frac{1}{8}$	15 „ 16	13
$\frac{5}{32}$	13 „ 15	10
$\frac{13}{64}$	10 „ 12	9
$\frac{1}{4}$	9 „ 10	$7\frac{1}{2}$
$\frac{9}{32}$	8 „ 9	$6\frac{1}{2}$
$\frac{21}{64}$	7 „ $7\frac{1}{2}$	6
$\frac{23}{64}$	$5\frac{1}{2}$ „ 6	5
$\frac{15}{32}$	$4\frac{1}{2}$ „ $4\frac{1}{2}$	$3\frac{1}{4}$
$\frac{15}{32}$	$3\frac{1}{4}$ „ $3\frac{1}{2}$	$2\frac{1}{2}$ to 3
$\frac{19}{32}$	$2\frac{1}{4}$ „ $2\frac{1}{2}$	$1\frac{1}{2}$ „ 2

Owing to metallurgical changes that take place when melting medium and high carbon steel with the blowpipe, the welds obtained are invariably unsatisfactory. As a general proposition, the lower the carbon content of the steel, the more successful the welding operation. It is possible to get fair results on medium steels, but a flux, rapid welding, and thermal after-treatment, which requires skill to properly carry out, are necessary.

The data at hand show that for welding medium carbon steel, welding wires having a carbon content ranging from 0·06 to 0·60 per cent. are of no particular value.

For welding medium and high carbon steel and worn surfaces where great resistance to abrasive wear is desired and where machining is not necessary, a welding wire containing 0·60 to 0·75 per cent. of carbon and 0·30 to 0·90 per cent. of manganese, or a special welding wire such as chrome-vanadium, is desirable.

Alloy steels, such as chrome and manganese steel, are weldable, provided the percentage of carbon does not bring them into the range of medium and hard steels, which is frequently the case. The welding wire should be of the same character as the steel, and a flux must be used. In the case of nickel steel it is necessary to use a flux which will form a varnish over the molten metal and prevent the absorption of the gases from the flame of the blowpipe. It is important to recognise that alloy steels are used largely because of the excellent physical properties that are developed by suitable heat treatment, and that the uneven heat treatment produced by welding temperatures may produce considerable variations in quality. Hence they should be welded with a full knowledge of the alloy and the results likely to be obtained. This also applies to the welding of stainless steel, which has recently been thoroughly investigated. The principal difficulty is the formation of the oxide of chromium which is dealt with by the use of a first-class flux. The method of applying the flux is an essential factor for success, and consists in coating the welding wire or rod and the underside edges of the sheets to be joined. To obtain an adhesive coating the wire and edges are first painted with a solution of silicate of soda and then sprinkled with the flux.

Cast-Iron Welding.

The two principal defects in cast-iron welding are the production of hard spots and blowholes in the weld and subsequent cracks or fractures in the weld or adjacent metal. The oxide formed must be removed or destroyed by the use of a flux. The welding rod must be of good material and specially made for cast-iron welding. One great trouble with cast-iron rods in general is that the quality is by no means uniform. This is especially true with the cheaper and uncontrolled products. Rods made from ordinary cast iron produce blowholes and hard spots. Special rods containing titanium, producing sound, soft, and reliable welds, are obtainable. Expansion and contraction should be considered as of great importance. Preheating should be used to some extent in all cast-iron welding. It is advisable to weld in position after preheating. The welder is protected by making use of asbestos sheet or simply plate. Specially designed blowpipes of considerable length are available for this class of work, and two or three welding rods are welded together. The parts must be thoroughly cleaned, and in the case of cracks their extension must be prevented by drilling holes a short distance from the ends in the direction the crack would follow. The weld should be arranged horizontally, and where this cannot be arranged carbon blocks should be used to prevent the metal flowing away. Carbon products, in the form of blocks, powder, or paste, play an important part in modern welding operations. They are far superior to fireclay or fire-bricks, which are liable to melt under the blowpipe and invariably cause blowholes. Carbon compound, in powder form, which can be made into a plastic mass with water, is valuable for making moulds, dams, etc., and for lining up repairs and holding parts in position. To protect machined surfaces during preheating operations, they should be coated with flaked graphite and oil. This can be made into a paste and painted on, or the surfaces can be oiled and the

graphite dusted on. The graphite must be coarse, as fine flake is not satisfactory. The flame must be held so that the tip of the white cone is between ¼ and ⅜ in. from the molten metal, the distance depending on the thickness of the metal. The after-treatment consists in annealing or allowing the metal to cool very slowly. In well-executed welds on cast iron the quality of the weld is generally superior to that of the metal of which the casting is made. The grain is finer and the welded zone is sound, homogeneous, and can be easily worked.

Certain cast irons of great strength and in which the carbon is in the combined state are difficult to weld. Cast iron which has been submitted to the heat of a fire for a considerable time is frequently unweldable. The metal in both cases melts under the blowpipe in a distinctly different manner from ordinary cast iron, and the welder should have no difficulty in recognising that the blowpipe should not be applied to make a joint. The bronze 'welding' of cast iron, iron, steel, etc., is a process in which the oxy-acetylene flame is used in conjunction with a copper-zinc alloy, such as 'Suder Bronze,' 'Sifbronze,' or manganese-bronze, to produce joints which would be difficult or expensive to obtain by the usual method of melting the metal of the casting. The procedure in making joints is very much the same as in actual welding. The 'V' opening need only be about 15°. The heat must be just right—too much will burn the bronze, too little will prevent any alloying—and the surfaces must be clean. It has been found in actual operations that the welding time is greatly reduced when the parts are prepared by sand-blasting. Extensive researches have been made on the bronze welding of cast-iron pipes.

Malleable Cast Iron.

It is difficult to produce satisfactory joints on malleable cast iron by welding. The welds are usually hard, brittle, and porous. The best results are obtained by brazing with the oxy-acetylene blowpipe, using the same methods of preparation as for cast iron, and using 'Suder' or 'Sifbronze' as a filling material. The two pieces to be joined are brought to a point just below fusion, great care being taken that they do not become fused. When the edges are at a right temperature, the rod of manganese bronze is fused into the groove with the aid of a good flux.

The introduction of acetylene for brazing purposes provides a fuel which has the highest known flame temperature and high calorific value. By using dissolved acetylene with a special brazing blowpipe no air-bellows or oxygen is necessary, as the blowpipe is atmospheric and a clean and relatively small flame of suitable power is obtained.

Aluminium Welding.

Sheet aluminium welding can be handled in very much the same way as steel as regards preparation and allowance for expansion and contraction. The principal difficulty lies in the formation of the oxide, which must be dealt with by an energetic and reliable flux. The filling material is pure aluminium wire; before starting to weld, the wire and parts to be welded must be thoroughly cleaned by scraping. A delicate touch and considerable practice are necessary, especially on thin material. Material under 22 gauge is best welded after flanging the edges. The flanged edges should practically have no radius, so as to leave the minimum of space between the underside of the sheets. The depth of the flange should be about two and a half times the thickness of the sheet. The white cone of the flame should be level with the surface of the plates and the blowpipe held so that the flame is inclined to the horizontal at about thirty-five degrees. If the methods are correct the upper and lower surfaces of the weld appear identical. The power of the blowpipe to be used is not in direct ratio to the thickness of the metal as in steel welding. For example, on 16 to 19 gauge material a blowpipe consuming 2 cu. ft. of acetylene per hour would be satisfactory, whilst for material ⅛ in. thick 10 cu. ft. is required, and for ¼-in. material 40 cu. ft. per hour. The flame must be carefully regulated, and the tip of the white cone should be from ¼ to ⅜ in. from the molten metal. After welding, the welds should be thoroughly washed with warm water and, where possible, internal strains should be removed by annealing. The structure and strength of the metal in the welded zone are improved by hammering when cold. Subsequent corrosion of the welded seams may be due to the physical condition of the aluminium sheet and the welds, and in the case of important work preliminary corrosion tests should be made on welded strips cut from the sheets.

Pure aluminium is not usually employed for castings subject to stress. In order to raise the tensile strength and increase the hardness varying percentages of zinc, copper, or nickel are added. There is an endless variety of aluminium alloys, but from a welding point of view they fall into two classes, viz., those containing zinc as their principal hardening medium and those containing copper. The material expands greatly and is very weak at high temperatures, consequently contraction strains are likely to produce cracks and distortion unless the work is properly handled. In welding castings—crank cases, for example—it is often necessary to preheat them either completely or partially. The preheating must be done carefully, otherwise the casting may collapse. For supporting the casting evenly and lining up, carbon putty is useful. For missing parts, and where the welder is not well skilled in this class of work, it is advisable to back up with sheet copper or galvanised iron. In rigging up jobs for repairs, care must be taken that expansion and contraction effects are not interfered with. The parts should be carefully cleaned and free from oil and grease. The repair of oil saturated castings is frequently one of considerable difficulty. Cleaning, by dipping in caustic soda, followed by washing in scalding hot water,

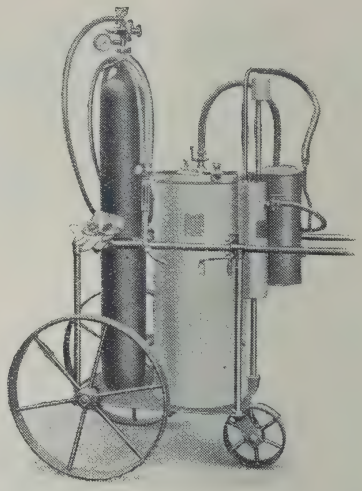
Cutting and Welding at Low Cost

THE cheapest way of obtaining Acetylene is to use a Carbic Low Pressure Plant and Produce your own from Carbic Cakes, a specially prepared and compressed form of Carbide.

CARBIC Cakes yield a guaranteed volume of gas of exceptional purity, and entirely without waste.

CARBIC Generators are portable, low in first cost, economical in working, and highly efficient at the weld. Being automatic in action, they need no attention while in operation, and maintain a regular supply of cool, pure gas at unvarying pressure.

WRITE for your complimentary copy of the NEW Carbic Cutting and Welding Book. Particulars of Carbic Flare Lights and Hand Lamps will also gladly be sent upon request.



Carbic Limited,

Specialists in Acetylene

(Dept. E.Y.),

and drying, bevelling to a larger angle than usual and sweating out the oil and scraping it away, indicate the methods which lead to successful repairs. A good grade of filling material of average composition is necessary; pure aluminium wire should not be used. The acetylene should be pure and the blowpipe should give a soft, non-oxidising flame. Two methods of welding are adopted, one known as the flux and the other as the puddle method. In the former a flux is used in the ordinary way and in the latter no flux is used, a steel rod and paddle being used to remove or break down the oxide and to smooth the weld respectively. All traces of flux must be washed off. The casting should be reheated slightly to remove any local strains and then allowed to cool very slowly. For finishing off a single cut-file or a 'dreadnought' file is most suitable.

The welding of the well-known aluminium alloy known as 'Duralumin,' which contains copper, manganese, magnesium, etc., is satisfactory or not according to the mechanical properties required in the joint. The alloy has important properties which are reduced, and in some cases almost eliminated, by welding operations. The metal should not be welded when the joints are subject to bending action, shocks, or when the full properties of the metal are desired.

The welding of aluminium-silicon alloys, such as Alpax, in the form of castings presents no particular difficulty. In sheet form, however, the difficulties are greater than with pure aluminium sheet, and the correct welding procedure must be followed. Bevelling for material slightly exceeding $\frac{1}{16}$ in. is advisable to obtain good penetration. A welding wire of Alpax and a good flux are essential.

Copper Welding.

Copper may be welded, but only satisfactorily where the operator is familiar with the technique. Many failures can be attributed to the commercial metal being in an unsatisfactory condition for welding. Material which may be satisfactory for brazing may prove quite unsuitable for welding. Where possible, a sample strip 2 or 3 ins. long should be tested by making a weld and applying a bending test. It is necessary to clean and bevel the edges and to support the underside of welds made on thin material, copper tubes, etc., by means of a mandrel consisting of an iron tube on which is wound or fixed asbestos, which must be perfectly free from moisture. Owing to its lack of strength when hot, the tacking of copper welds should be done carefully. For the same reason welds should not be started at the edges of the sheets, but at a point about one-third the length of the seam. The power of the flame should be practically the same as that used for welding steel of the same thickness. The flame must be carefully regulated. The melting should not be too rapid or too slow. Without a correct welding rod, which contains a small quantity of phosphorus, it is impossible to satisfactorily weld copper. A flux is useful. Preheating to avoid adhesion is necessary. The tip of the white cone should be about $\frac{1}{4}$ in. from the surface of the molten metal. The welds should be hammered at a dull-red heat to improve their ductility and strength, and afterwards annealed. The technique for the repair of copper fireboxes and tube plates has been worked out and applied with great success. A good sense of fusion, the addition of the metal in thin layers, and satisfactory equipment are essential for success. Welds can be obtained with mechanical properties almost identical with those of the metal welded. Such welds can be planished, stamped, spun and, in general, submitted to the ordinary workshop operations carried out on sheet copper.

Brass and Bronze Welding.

Brasses and bronzes are only welded indifferently without the correct welding wire or rods. The filling material should be practically of the same composition as the metal to be welded, which, in the case of brass, should contain a little aluminium, and in the case of bronze a little phosphorus and traces of aluminium. Bronze filling materials are cast. Fluxes should be used in both cases, and the power of the flame is less than that used for the same thickness of copper—that is, distinctly less than for steel plates of the same thickness. The regulation of the flame is very important: a slightly oxidising flame will give a surface free from wrinkles. The position of the flame is the same as for copper. The after-treatment of the welds consists in annealing at definite temperatures. Identification of the particular brass or bronze to be welded is important in view of the importance of choosing the correct welding wire or rod, and the subsequent heat-treatment which is necessary. Reclaiming castings and repairing worn or broken parts, such as gear wheels, bearings, etc., constitute the general run of the work on bronzes. In the case of castings similiar methods to those outlined for the repair of cast iron are necessary.

Lead Welding.

The oxy-acetylene blowpipe is rapidly supplanting the older methods of welding lead, or 'lead burning,' as it is generally called. It has proved superior in convenience, quality of joints, and economy. A small type of blowpipe is required, consuming from $\frac{1}{2}$ to 6 cu. ft. per hour. When it is necessary to fill up a hole or to build up any part of a lead object, the work is facilitated by using a mould or a backing of steel plate. When welding patches in repair work avoid rectangular patches on vertical faces, which make two edges of the patch horizontal. The patch should be made lozenge shape, so that the welds are done on the incline. The welding wire or rod should be of the same metal as the sheet. Special outfits have been designed for lead burning. using dissolved acetylene; they are very compact and portable.

Nickel Welding.

Nickel when melted has the property of readily absorbing gases, especially oxygen. Various methods have been tried to protect the molten metal from the gases of the blowpipe and to prevent their absorption. The welds obtained are very porous, and it is extremely difficult to obtain satisfactory welds. A method which has given fair results consists in placing the two parts to be welded on a heated anvil and then heating the parts to a white heat with the blowpipe, afterwards carefully hammering the parts together. The key to the production of sound welds lies in the deposition of metal which is metallurgically sound. It has recently been proved that the welding of nickel and its commercial alloys—such as Monel metal—can be satisfactorily accomplished by the use of a flux, in which manganese acts as a desulphurising agent, or a borated acetylene flame.

Machines for Welding.

Acetylene welding machines for the manufacture of tubes have been in use for many years. The development of automatic welding machines for the manufacture of tanks, etc., is more recent. For repetition work machines have been designed which accomplish the work in less time with comparatively unskilled men. The machines consist of two parts, (*a*) holding device for the work, and (*b*) apparatus for moving the blowpipes, with or without oscillatory motion, over the seam.

Recent developments in welding machines have been mainly in the direction of the use of multi-jet blowpipes. In order to obtain speed it was recognised that more than a single jet of flame should be employed, and from two jets in tandem it has become customary to employ a large number of jets extending for a considerable distance along the line of the weld. The defects of this method have been overcome by distributing the heat on both sides of the centre line of the seam. The welded section produced in this way is wider, stronger, and more certain to penetrate than is the case with the narrow weld made by a central line of flame.

Training Welders.

An oxy-acetylene welder has been defined as a person who has the requisite manipulative skill and technical knowledge successfully to operate welding and cutting apparatus, and, at the same time, has skill in the operation of hand tools used in the preparation and finishing of the work in connection with welding, and also has a reasonable amount of ingenuity. He must also have a knowledge of accuracy commensurate with the type of work to be welded. Naturally, a trade in which so much depends on the personal equation has drawn attention to the need of training men to produce sound work. No doubt the best method is that which expounds principles followed by practice under expert supervision. Welding skill grows rapidly under a well-worked-out system of exercises which aim at developing skill in making typical welds on various metals. Testing the welds is also an important requisite of a training course. Classes for training welders are held in the principal centres, and manufacturing concerns who train their workmen must follow methods depending upon the size of shop and class of work.

A common error is to attempt work, especially repair work, in a shop where the tools and apparatus for successful all-round welding are not provided, or to endeavour to repair jobs which are beyond the capacity of the welder. It is much more economical, in such cases, to hand over work of this character to firms, such as *Barimar Ltd.*, who have a world-wide reputation for repairs of all kinds, especially large castings which frequently must be welded *in situ* and require specialised knowledge and a choice of the most suitable welding process. A firm such as this, specialising in general repairs, have the necessary equipment for carrying out and testing the work, and welders who are not mere blowpipe operators.

Testing Welds.

The importance of testing welds has, in recent years, become very great. It is well known that the quality of a weld cannot be assumed from the general appearance, finish, etc., although considerable information can be obtained from the visual inspection of welds. At the present time the usual methods of testing include tensile and impact tests on specimens welded under identical conditions, microscopic examinations of specimens, bending and hammering tests and X-ray examination. In the latter the actual welds can be examined, and flaws, blowholes, and other defects discovered. Recent investigations indicate that electrical and magnetic test for the non-destructive examination of welds will soon find commercial application. In fact, simple and portable apparatus based on the magnetic properties of iron and steel is now available for the non-destructive examination of welds on iron and steel of any thickness.

The American Bureau of Welding have drawn up Standards for Testing Welds which are intended primarily to serve as a standard uniform basis for testing and comparing sample welds as distinguished from welds on structures. The testing of the latter must necessarily be by non-destructive methods, which would therefore be, in general, quite different from those employed in examining sample welds made for the purpose of testing a welder's proficiency, comparing welding wires, or comparing welding methods. For the shop standard a bending test is recommended; for the commercial standard, a bending and tensile test on approved lines.

Miscellaneous Applications.

There are numerous applications of the oxy-acetylene process not included in the term welding, but which have a direct or indirect connection with it and are worth consideration. The oxy-acetylene flame, for example, is a convenient and simple method of applying local heat for numerous workshop operations, such as forging, straightening, riveting, expanding for shrinkage fits, heat-treatments, etc.

Brazing operations are more efficiently carried out with the oxy-acetylene flame than by the older methods. Case-hardening and surface hardening can also be efficiently and economically done with the flame.

OXY-ACETYLENE CUTTING.

Wrought iron, steel, and steel castings can be cut with the ordinary cutting blowpipe, and with a special cutting blowpipe or the ordinary cutting blowpipe operated in a special manner, cast iron can be cut.

The cutting blowpipe usually consists of a compound jet made up of one or more heating flames with a pure oxygen jet in the centre. The purity of the oxygen is of much greater importance when used for cutting than when used for welding. As the purity decreases the oxygen consumption and time increases, and the speed of cutting decreases as the following figures, which represent tests on steel plates 5 feet long by 1 inch thick, show :—

No. of Test.	Purity of Gas. Per cent.	Time in Seconds.	Oxygen Consumption in Cu. Ft.	Remarks on Cuts.
1	99·7	280	8·0	Very smooth and clean.
2	99·4	291	8·8	Smooth.
3	99·1	315	9·8	Satisfactory.
4	98·0	334	11·3	Good but rough
5	96·0	365	13·2	Not smooth.
6	95·0	412	15·4	Very irregular.
7	90·0	644	20·0	Rough, surface bad.
8	87·0	675	23·0	Very rough, surface bad.
9	85·0	696	25·8	Very rough, unsatisfactory.
10	82·5	—	28·4	Very rough & not through.

A spot on the metal is first heated to a bright red heat with the heating flame, and then the oxygen jet is turned on. It has been proved that only partial combustion takes place, the phenomenon of cutting being really a disintegration by the current of gases from the blowpipes. The oxy-hydrogen or oxy-coal-gas flame is often used for cutting in place of acetylene. Material up to 36 ins. has been cut. The same acetylene equipment is used for cutting as for welding. For heavy cuts special oxygen regulators are required. There are two kinds of cutting blowpipes, known as the 'central' and 'following jet' types. Mechanical contrivances have been devised for special forms and shapes and for heavy cutting. Automatic cutting machines using the oxy-acetylene or oxy-coal-gas blowpipe, with or without preheated cutting oxygen, have reached a high degree of perfection. These machines usually have the full range of movements found on a universal machine tool, and have a degree of accuracy such that accurate gear teeth can be cut, and any desired number of thousandths can be left for finishing.

APPROXIMATE RESULTS FOR STEEL CUTTING.

(*British Oxygen Co., Ltd.*)

Thickness of Material.	Nozzle.		Speed of Cutting.	Pressure of Oxygen at Regulator.	Gas Consumption. Cu. ft./hr.	
	Size.	Distance from Work.			Oxygen.	Acetylene.
Ins.	Ins.	Ins.	Ft./hr.	Lbs./sq. in.		
$\frac{1}{4}$	$\frac{3}{3\cdot2}$	$\frac{3}{16}$	66	20	42	16
$\frac{1}{4}$	$\frac{1}{16}$	$\frac{3}{16}$	*80*	*20*	*110*	*16½*
$\frac{1}{2}$	$\frac{1}{3\cdot2}$	$\frac{3}{16}$	58	25	50	20
$\frac{1}{2}$	$\frac{1}{16}$	$\frac{3}{16}$	*65*	*25*	*135*	*21½*
$\frac{3}{4}$	$\frac{1}{16}$	$\frac{1}{4}$	55	32	142	23
$\frac{3}{4}$	$\frac{1}{3\cdot2}$	$\frac{3}{16}$	*35*	*35*	*62*	*23*
1	$\frac{1}{16}$	$\frac{5}{16}$	48	35	150	24
$1\frac{1}{4}$	$\frac{1}{16}$	$\frac{3}{8}$	44	35	150	$24\frac{1}{2}$
$1\frac{1}{2}$	$\frac{1}{16}$	$\frac{3}{8}$	40	40	175	25
2	$\frac{1}{16}$	$\frac{1}{2}$	30	45	190	28
3	$\frac{1}{16}$	$\frac{1}{2}$	24	55	210	31
4	$\frac{1}{16}$	$\frac{1}{2}$	20	60	230	36
5	$\frac{1}{16}$	$\frac{5}{8}$	17	65	250	40
6	$\frac{1}{16}$	$\frac{5}{8}$	15	70	270	43

The above figures are based on actual cumulative results and the chief variation to be expected is the cutting speed, which will vary according to the nature of the work, experience of the operator, etc.

Figures shown in full are recommended ; figures in italics may be used if desired.

HEAVY STEEL CUTTING.

Material Thickness.	Nozzle Size.	Distance of Nozzle from Material.	Oxygen Pressure.	Approximate Speed of Cutting.
Ins.	Ins.	Ins.	Lbs./sq. in.	Ft./hr.
7	$\frac{3}{3\cdot2}$	$\frac{3}{8}$	70	13
8	$\frac{3}{3\cdot2}$	$\frac{3}{8}$	75	12
9	$\frac{3}{3\cdot2}$ or $\frac{7}{0\cdot4}$	$\frac{3}{8}$	85	11
10	$\frac{7}{0\cdot4}$	$\frac{3}{8}$	95	10
12	$\frac{7}{0\cdot4}$ or $\frac{1}{8}$	$\frac{7}{16}$	120	8
14	$\frac{1}{8}$	$\frac{7}{16}$	150	6
16	$\frac{1}{8}$	$\frac{7}{16}$	180	5

Blowpipes can be obtained for cutting steel under water. Under-water cutting is based on the fact that the water must be forced away from the heating flame and cutting jet.

Compressed air has been used for this purpose, and one type of under-water cutting blowpipe makes use of the products of combustion. The cooling action of the water necessitates using a heating flame five to seven times as powerful as that used for cutting the same thickness of material in the ordinary way. With an efficient arrangement an ordinary hand-cutter can be adapted for cutting under water. In salvage work steel plates have been cut at a depth of 40 ft. Various devices for lighting the flame under water when it becomes extinguished have been successfully introduced, being in the form of a pilot light burning continuously and forming part of the blowpipe. The British Oxygen Co. have found, with their under-water cutting blowpipe, that it is possible to cut as fast, or even faster, under water than in the dry.

Cast iron can be cut by means of the oxygen lance or by a special oxy-acetylene blowpipe. In the former case an iron tube from 6 to 12 feet long, $\frac{3}{8}$ in. external and $\frac{3}{16}$ in. internal diameter, containing three wires of 12 gauge, is supplied with oxygen at a pressure of from 70 to 150 pounds

per square inch, according to the thickness to be cut. The point at which the cut is to be started and the end of the tube are raised to a red heat by means of an oxy-acetylene blowpipe, the oxygen turned on and the heating blowpipe removed. Combustion of the cast iron and the tube proceeds rapidly; it takes 20 seconds to penetrate a piece of cast iron 4 inches thick and less than 2 minutes for material 24 inches thick. In the second method a cutting blowpipe with a flame having a distinct excess of acetylene is used, or a blowpipe in which the cutting jet is modified and not the heating flame. In the latter type a certain quantity of acetylene is introduced into the cutting jet and leads to an increase in the temperature of the oxygen.

The following is an abstract from a manufacturers' table of cutting data:—

APPROXIMATE RESULTS FOR CAST IRON CUTTING.

(British Oxygen Co., Ltd.)

Metal Thickness.	Nozzle.		Oxygen Pressure.	Length. of White Cone.	Approx. Speed of Cutting.	Gas Consumption. Cu. ft./ft. run.	
	Size.	Distance from Work.				Oxygen.	Acetylene.
Ins.	Ins.	Ins.	Lbs./sq. in.	Ins.	Ft./hr.		
Up to 1½	3/64	3/8	110	2	7	20	7·2
1½— 3	1/16	1/2	120	3	6	40	12·5
3— 5	3/32	1/2	130	3½	5	55	17·6
5— 8	3/32	5/8	160	4	4	80	23
8—11	7/64	5/8	150	4	2½	200	48
11—14	1/8	3/4	150	4	2	300	75
14—16	1/8	3/4	160	4	1½	400	105

The above pressures, speeds, and consumptions are merely given as a guide to indicate the results obtained on cast-iron cutting and they will vary according to the composition of the iron, etc.

ELECTRIC WELDING.

Electric welding processes can be placed in two distinct groups, one producing heat by the resistance of the metal being welded to the passage of the current, the other using the heat of the electric arc. They are known as Resistance Welding and Arc Welding, respectively. These two main groups have formed the basis for many processes of welding. The differences rest entirely on methods and special applications. The subdivisions are as follows:—

Arc Welding.

(1) Carbon or graphite electrode.
(2) Metallic electrode.
  (*a*) Bare electrode.
  (*b*) Coated electrode.
  (*c*) Covered electrode.
(3) Electric blowpipe.
(4) Atomic hydrogen.
(5) Shrouded arc.
(6) Gas shielded.

Resistance Welding.

(1) Butt welding.
  (*a*) Flash welding.
  (*b*) Upset welding.
  (*c*) Automatic butt or contact flash.
(2) Mash welding.
(3) Seam welding.
  (*a*) Butt seam welding.
  (*b*) Lap seam welding.
  (*c*) Bridge seam welding.
  (*d*) Flash-seam welding.
(4) Percussive welding.
  (*a*) Electro-static.
  (*b*) Electro-magnetic.
(5) Spot welding.
  (*a*) Lap spot welding.
  (*b*) Bridge welding.
  (*c*) Button welding.
  (*d*) Disc depression welding.
  (*e*) Point welding.
  (*f*) Multiple point welding.
  (*g*) Multiple electrode welding.
  (*h*) Ridge welding.
  (*i*) T-spot welding.
  (*j*) Duplex spot welding.

The many systems of welding which have developed from these main groups are generally associated with the inventor's name or company exploiting the process, such as:—

Benardos System. Thomson System. Daysohms System. A.C. Welding System.
Slavianoff System. Alloy Welding Processes. Cyc-Arc Process. Fluxode System.
Kjellberg System. Plastic-Arc System. Atomic-hydrogen Process. Electronic Tornado Process.
Zerener System. Quasi-Arc Process. Ferro-Arc Process.

ARC WELDING.

Commercial efficiency of arc welding processes is estimated by the relation that the quality of the work bears to the cost. The principal factors which decide the quality of the work are: (*a*) electrodes; (*b*) current (D.C. or A.C.); (*c*) welding equipment; and (*d*) efficiency of the welder. In assessing the cost the principal factors are: (*a*) capital expenditure; (*b*) depreciation and maintenance charges; (*c*) wages; (*d*) cost of electrodes and, (*e*) cost of electrical energy. The speed of welding enters into the question of cost provided increased speed is not obtained at the expense of welding efficiency. The absolute requisites for good work are: (*a*) low voltage; (*b*) short arc; and (*c*) constant heat per unit area in the weld. An arc welding circuit should possess the following characteristics: (1) ease of arc establishment when the work and electrode are cold; (2) freedom from undue tendency to freezing of electrode or extinguishing of arc with maintenance of short arc streams; (3) stable arc with maintenance of short arc streams; (4) limited current increase with growth of liquid globule; (5) limited increase of current at the instant and during the period the globule short circuits the arc stream; (6) the arc voltage should increase rapidly at the instant of globular detachment or on breaking a momentary short circuit in order to facilitate re-establishment of a stable arc. The subject of welding nomenclature, definitions, and symbols is receiving consideration.

Carbon Arc Welding.

The characteristic principle of this process, commonly known as the Benardos process, is that an electric arc is held between the metals to be joined, which forms one electrode of the circuit, and a carbon rod or pencil manipulated by the welder which forms the other electrode. By placing the carbon electrode in contact with the metal, thus closing the circuit, and instantly withdrawing it again, an electric arc is formed between the two electrodes and, owing to the high temperature of the arc, the metal is melted. Steel up to $\frac{3}{32}$ in. is satisfactorily melted together without using a filling material, but for greater thicknesses a 'melt bar' is melted into place by the heat of the arc. Experience has shown that the metal to be welded should be the positive electrode, and the carbon the negative electrode. If this order is reversed, a shorter arc is obtained and particles of carbon can enter the molten metal and cause brittleness.

The current used is direct, the voltage being from 60 to 90, and the amperes vary from 250 to 600, depending upon the thickness of the metal.

The use of graphite electrodes in place of hard carbon electrodes is increasing as the merits of the graphite electrode are more widely known. The chief advantages are: (*a*) breakage in handling and in operation is appreciably reduced; (*b*) breakage and cracking due to sudden changes of temperature is eliminated; (*c*) less carbon is carried into the weld; (*d*) the arc is much steadier; (*e*) the life is from two to three times as long as for an amorphous carbon electrode of the same diameter; (*f*) electrical conductivity is four times that of the carbon electrode of the same cross-section, consequently the heating caused by resistance is negligible and much higher current densities can be carried. Considerable development is being made in the art of carbon arc welding where graphite electrodes are used. The single or double graphite arc has proved useful in the welding of non-ferrous metals. Automatic carbon electrode welding machines are now extensively used owing to the increased speed and lower costs obtained, as compared with hand work.

A recent development, the results of which it is claimed will be far-reaching, is the Electronic Tornado process of automatic carbon arc welding, in which control of the arc is established by super-imposing a strong magnetic field on the arc flame. This control permits the arc to travel through the various fields without disturbance, and the arc is given a gyratory motion of great velocity which also tends to hold it in a straight line. Increased strength, ductility, and high welding speeds are obtained. The process can be applied to light sheets or heavy plate.

Metallic Arc Welding.

The use of metallic electrodes for arc welding has proved more satisfactory than the use of carbon or graphite electrodes, which necessitate feeding the new metal into the arc by means of a rod or wire. A very wide variety of metal electrodes are used and can be classified as follows: (*a*) bare wire; (*b*) coated electrodes manufactured by dipping, painting, or spraying with a liquid; (*c*) covered electrodes, which are wrapped with a refractory material or otherwise encased in a much heavier covering than that used for coatings. They can also be classified as: (*a*) heavy slag depositing electrodes; (*b*) light slag depositing electrodes; (*c*) flux-coated electrodes which deposit no slag; and (*d*) bare wire. Sheathed electrodes have a flux between a metal core and sheath, whilst composite electrodes have one or more conducting materials combined mechanically with the flux. The effect of surface materials on electrodes from the standpoint of some of the scientific laws governing the metallic arc has been investigated and it has been shown that the presence of non-metallic materials on the surface is required. Generally speaking, there is a sphere of utility for each type, and provided care is exercised in their selection, a weld of maximum efficiency should be obtained. Information on automatic and semi-automatic metallic arc welding is given on p. 2788.

Bare Electrode.

The Slavianoff System, using a bare metal electrode, has not been developed in this country to any extent. There is considerable discussion as to the efficiency of bare electrodes, and although it may be possible to successfully weld mild steel with such electrodes, where toughness is desirable or necessary, or for the welding of steel alloys, a coated or covered electrode will give better and, in many cases, the only successful results. The decision of Lloyd's in approving the use of covered electrodes has not caused the adherents of the bare-metal electrode to abandon their position. The bare electrode imposes a minimum thermal load, but requires the presence in the equipment of a high stabilising factor. The following is an abstract from a specification for bare iron and steel electrodes for welding mild steel, steel forgings and castings, plates, bars, etc.:

Carbon	0·06	per cent.	maximum.
Manganese	0·15	,,	,,
Phosphorus	0·04	,,	,,
Sulphur	0·04	,,	,,
Silicon	0·08	,,	,,

In the hands of an experienced welder electrodes should demonstrate good weldability in 'flat' and 'overhead' positions, and should pass through the arc smoothly and evenly without any unusual characteristics.

The data at hand show that bare steel electrodes having a carbon content between 0·18 and 0·85 per cent. are of no particular value.

Coated and Covered Electrodes.

The use of coated and covered electrodes aims at improving the metal in the weld, permitting the use of alloy steels, non-ferrous metals, etc., as electrodes, facilitating electrode manipulation and the use of alternating current. Covered electrodes may be placed in two general classes, the first class being the electrode which has a heavy covering of scientifically prepared material containing a deoxidiser. The second class of covered electrode is of the type which has a very thin coating on the wire and aims at obtaining the same results as the heavy covered electrodes without manipulating the heavy coating of slag deposited during the welding operation. It is possible to obtain as many as twenty different types of flux-covered electrodes, each specially designed for depositing a particular material. As a result of research work, electrodes are now available for the purpose of welding and depositing non-ferrous metals.

The percentage, by weight, of an electrode which passes over into a weld, sometimes called the deposit efficiency of the electrode, is affected by the following factors: (*a*) current, but not current density; (*b*) polarity; (*c*) thickness of the work; (*d*) chemical composition of the electrode; (*e*) surface materials of electrode; (*f*) occluded gases, slag inclusions, etc.; (*g*) arc length. Experiments so far recorded indicate that a good commercial electrode will show from 80 to 90 per cent. deposit efficiency, whilst a poor rod may show as little as 50 to 60 per cent. The bearing of this on welding costs merits attention.

Kjellberg System.

The effect of refractory coverings on the metal electrode was first discovered by Kjellberg. In the Kjellberg process, controlled by the *Anglo-Swedish Electric Welding Co., Ltd.*, the steel rod is covered with a coating or sleeve of normally non-conducting materials, the function of the cover being, amongst other things, to direct the metal where it is required, to protect the fused metal from oxidation, and to make up the loss in the arc of certain constituents of the iron or steel forming the object.

In carrying out the process the covered rod is held in a clip or holder connected to a continuous current supply, and forms the positive pole, the object forming the negative, though in some cases the poles are reversed.

The covering is removed from the end of the rod to enable the current to pass, and an arc is struck between the rod and the object. As soon as the arc is struck a portion of the metal of the object, having an area approximately equal to the section of the rod, fuses together with metal from the end of the rod, and at the same time the covering, which is of a friable nature, partly fuses and breaks away at the same rate as the metal of the rod is deposited. In this way metal can be gradually deposited on an object until a sufficient quantity has been obtained for the purpose required. From time to time the deposited metal is hammered so as to consolidate it in exactly the same way as a weld made in the fire.

A further advantage of the covering on the rod is that the tensile strength of the weld can be varied within certain limits to suit the purpose required. For example, by this process a tensile strength of from 20 to 35 tons per sq. in. can be obtained. It is possible also to obtain various degrees of hardness merely by altering the composition of the covering.

'Quasi-Arc' Electrodes.

These electrodes are the special product of *The Quasi-Arc Company, Limited*, and are patented throughout the world. The company also supply special plants which enable electric arc welding to be carried out with both A.C. and D.C. supplies of any voltage in the most economical and efficient manner.

'Quasi-Arc' Electrodes consist of a special steel wire coated with a mineral flux having distinct physical and chemical properties whereby a weld of the highest mechanical strength and purity is obtained.

In making a weld or reinforcing a worn surface the electrode is held in an insulated holder connected by a flexible lead to the positive pole of an electric generator, and an arc is struck between the electrode and the work which carries the negative connection. The welding operation is continued by holding the point of the electrode just under the surface of the molten slag and feeding down uniformly the electrode as the metal is deposited on the work.

The flux covering of the 'Quasi-Arc' Electrode has special properties to enable a low current to be used in fusing the electrode. The fused covering is acid in reaction, automatically removing any mill scale or iron oxide from the work; it is also reducing in its chemical character, so that it absorbs oxygen, and prevents atmospheric gases from causing defects in the weld metal and at the weld junction. The electrode therefore deposits a maximum possible amount of metal free from defects with a low current consumption, so that welding is not only reliable but very economical. The aluminium wire incorporated with the electrode further prevents oxidation of and removes gases from the weld metal. The low current used not only gives economy but prevents local overheating and embrittleness in the adjacent steel of the work, so that the weak brittle zone formed in the work when using many other types of electrodes is absent.

The metallurgical principles of the 'Quasi-Arc' Electrode follow closely those used in modern steel-melting practice.

Apart from Mild Steel Electrodes, the company manufacture special electrodes for welding Cast Iron, Carbon Steel, Manganese Steel, Stainless Steel; also 'Mangecross' Electrodes used for welding and reinforcing worn or fractured Manganese Steel, and 'Uranium' Electrodes which are suitable for welding work to be subjected to stresses at high temperatures, such as hot forging, flanging, etc.

The following table gives the comparative strength of riveted joints and joints made with 'Quasi-Arc' Electrodes. These figures are the results of official tests carried out by Lloyd's Register of Shipping, and it was on the excellent results obtained that 'Quasi-Arc' Electrodes were the first to be approved for welded ship construction.

TABLE SHOWING COMPARATIVE TENSILE TESTS OF LAP JOINTS OBTAINED BY RIVETING AND THOSE OBTAINED WITH 'QUASI-ARC' MILD STEEL ELECTRODES.

WELDED WITH 'QUASI-ARC' ELECTRODES.

Specimens of Mild Steel.	Dimensions. Overlap.	Breadth.	Thickness.	Sectional Area. Sq. in.	Tons. Max. Stress. Total.	Per sq. in.	Remarks.

The use of 'Quasi-Arc' Electrodes has been authorised by the British and Foreign Admiralties, Lloyd's Register of Shipping, the British Corporation for the Survey and Registry of Shipping, Det Norske Veritas, and Nederlandsche Scheepvaart-Inspectie Bureau, for use in the more important parts in ship construction.

'Quasi-Arc' Electrodes were exclusively employed in the construction of the all-welded motor ship *Caria* (ex *Fullagar*), of 400 gross tonnage. This vessel, built in 1920, has each year successfully passed Lloyd's Annual Survey, and is at present in service at British Columbia, having been recently renamed *Shean*.

Among later achievements by the use of 'Quasi-Arc' Electrodes is the application to a completely welded 3,000,000 cu. ft. gasholder, 200 ft. in diameter, 100 ft. high, with three lifts. Since this gasholder was satisfactorily completed, others have been constructed by the same method, together with the whole of the necessary framework. In addition, gasworks plant, including retort houses, condensers, gas mains, etc., have also been welded with 'Quasi-Arc' Electrodes. Hydro-Electric Pipe Lines have also been completelv welded with 'Quasi-Arc' Electrodes and a number of oil storage tanks, the largest being 140 ft. in diameter, with a capacity of 3,000,000 galls.

'Quasi-Arc' Electrodes are used in all the Royal Dockyards and by the principal railway and tramway companies, collieries, mines, engineering firms, and shipyards in Great Britain and abroad.

An impact or alternating impact and bending test gives a much better measure of the quality of a weld, especially the toughness, than a tensile test. Moreover, such a test conforms more to service conditions. A 'Quasi-Arc' weld being of sound and pure metal gives a very high result under such a test, whereas a weld made with an electrode not having a special reducing flux gives a value, due to the oxide defects present in the metal, sometimes a third of that given by a 'Quasi-Arc' weld.

In view of the importance which the subject of corrosion bears to that of welding, the following notes on this matter may be added :—

Fundamentally, corrosion is electrolytic in character, and depends on the difference in potential of contiguous areas.

Commercial iron and steel contain areas which in the presence of an electrolyte (which may be merely atmospheric moisture) are capable of forming voltaic circuits, the necessary conditions being afforded by the presence of small defects of iron oxide, etc., or by local conditions of strain in the metal itself. These impurities or strains give rise to areas of higher electrolytic potential, and form electro-positive points which are first attacked by the corroding agent. Thus, in a caulked joint, corrosion will commence at the caulking, and similarly a riveted joint will be attacked round the rivet head, owing to the local strains in the metal at these points.

In a welded joint, if the metal at the weld be less pure than the surrounding metal, the weld will be first attacked. Similarly, if the added metal be not homogeneous, local differences in potential in the weld itself will cause corrosion at the weld.

A microscopic examination of the metal deposited by 'Quasi-Arc' Electrodes shows it to be of great purity, and the usual laboratory tests show it to be always electro-negative to the surrounding metal. Hence it follows that this weld metal will have a high factor of resistance to corrosive influences.

In order that the best results may be obtained with 'Quasi-Arc' Electrodes it is essential that the electrical conditions be satisfactory. The Quasi-Arc Company have carried out a considerable amount of research work in order to determine the best designs for various types of plant. Although primarily the electrode governs the quality of work carried out by the arc welding process, it is of great importance that the plant be able to provide the correct amperage for the electrode in use, and that the arc remain stable at this current. The Quasi-Arc Company supply special D.C. generators of the drooping voltage type for single operator installations, and also constant voltage machines for multiple welder sets which fulfil these conditions in every way. These can be supplied as motor generators for A.C. or D.C. supplies or self-generating units driven by internal combustion engines.

The company have also paid particular attention to static transformer equipment for A.C. supplies, and can offer sets with which it is possible to carry out with 'Quasi-Arc' Electrodes welding of quality equal to that effected with a D.C. current.

They supply a welding unit for A.C. welding of particular interest, which is known as a Compensated Rotary Transformer. This machine supplies an alternating current to the arc, and generally has the economic advantages of static transforming plant. It has, however, several additional features which render it suitable for use on supply systems where static plant is not advisable. These may be summarised as follows : (1) The load taken from a polyphase supply is perfectly balanced ; (2) the power factor is of a value equal to that taken by well-designed induction motors ; (3) the ease of welding operation is increased by supplying the arc with current at a frequency three times that of the frequency of supply.

All 'Quasi-Arc' plants have been designed to obtain a maximum electrical efficiency with the simplest methods of control, so that the welder can adjust his welding current without difficulty and without electrical knowledge.

Alloy Welding Processes System.

'A.W.P.' electrodes are flux-covered, and have, in general, a spiral winding of asbestos yarn as a basis of the covering. Asbestos in itself is a flux, as it fuses and combines with iron oxide, forming a compound silicate, which reaction assists the operation of the flux coating. This spiral asbestos winding makes an excellent vehicle and support for the covering, which contains various valuable constituents, and is the chief feature of 'A.W.P.' electrodes. A suitable binder is used, making a tough-coated and concentric sheath to the metal core. These electrodes, therefore, travel and handle without damage to the covering. They are approved by Lloyd's Register of Shipping, the British Corporation for the Survey and Registry of Shipping, and Bureau Veritas, and give equally good results on either direct or alternating current.

The chief problem in electric arc welding is to prevent as far as possible the partial combination of the molten metal with oxygen and nitrogen—in other words, to avoid the formation of metallic oxides and nitrides, as these compounds are, in general, very detrimental to the success of welding.

By the aid of the flux covering, the molten metal is shielded from contact with the air, and if properly chosen it also serves the purpose of disposing of whatever oxides or nitrides may have unavoidably formed.

These fluxes, however, when carefully chosen not only tend to eliminate undesirable elements in the welded metal, but can be made effective in producing any desirable chemical composition in the deposited metal.

The 'A.W.P.' process has made it possible to lay down deposited metal of any predetermined composition, and to duplicate in the weld such metals as manganese steel, high-carbon steel, high-speed steel, stainless steel, etc., and other steels of very special qualities, which it would be impossible to secure with an electrode having a core of alloy steel. This subject is fully dealt with in the company's bulletins, which can be obtained on application.

'A.W.P.' electrodes are made in over twenty different types to suit all classes of work.

The growing importance of arc welding in engineering operations has caused *Alloy Welding Processes, Ltd.*, to give special attention to the design and construction of welding generators, which besides being light in weight, and therefore easily portable, will be capable of meeting every requirement of the welder in regard to its ability to handle electrodes of any make and any size within the range at present manufactured.

The 'A.W.P.' patent welding generator is a plain shunt-wound machine without separate exciter, or reverse compound winding. It is of the drooping characteristic type, having an open circuit voltage of approximately 70, which, however, drops to the pressure required at the arc immediately welding commences.

The machine can be adjusted, by means of a shunt regulator, to suit any size of electrode at present made.

On top of the dynamo frame is fixed a casing containing an oil-immersed transformer, the primary of which is connected in series with the main circuit and the secondary connected in the shunt field circuit.

The object of this transformer is to inject voltages into the shunt winding during sudden changes of load in the main circuit. This it does so effectively that the tendency for the main current to vary is checked immediately, in consequence of which a very stable arc is obtained. With a machine of this description there is a complete absence of spluttering at the arc, and the metal deposited is homogeneous and free from holes or sponginess.

The 'A.W.P.' dynamo can be supplied direct coupled to engine-driven plants for portable use, as motor generator sets fitted with either an A.C. or D.C. motor, or arranged for belt drive.

Alloy Welding Processes have also specialised in multi-operator machines for three welders and welding with alternating current, and are the proprietors of the Daysohms patent A.C. welder system, which is as follows:—

Daysohms' System.

This system is designed to work on ordinary alternating current supply circuits, and is portable or stationary as desired. One of the advantages claimed is the special adaptability of the device for the efficient welding of very thin metal; strips of mild steel, No. 20 S.W.G., have been welded in angle form at the rate of 1 ft. in 2 mins., the current being 27 amperes at 65 volts on open circuit with a power factor of 0·45. The supply current is transformed to the necessary voltage and then passes through a choking coil. This has a straight core, with pivoted keeper which can swing, the speed of its movement being controlled by a dashpot. Limits can be set to the movement on each side by means of cam-form stops. With passage of current the keeper of course tends to be attracted towards the core, and the nearer it approaches, the lower the flow of the current, owing to the increased choking effect. The limit of the approach is set by the adjustable cam, and in this way any welding current within the limits can be obtained. The other cam, which controls the striking current, similarly regulates the distance by which the keeper can move away from the core by gravity or spring. As has been stated, the speed of the movement is controlled by the dashpot, and this can be regulated by means of a perforated disc in the piston. Consequently both striking and welding currents can be adjusted independently, and the keeper is free to move between the stops under the control of an adjustable dashpot, so that the characteristic curve connecting volts and amperes is the resultant of the two curves which would have been obtained if the keeper had been fixed in either position. The consequence is that it is possible

to weld with a lower open-circuit voltage and, in addition, to weld thinner material without burning through, as the striking current can be set so as to be very little in excess of that required for the actual welding operation. In working the firm recommend that the current for welding should be adjusted first and then the striking current reduced until there is just sufficient excess to enable the arc to be struck easily.

These welding machines are available in two standard sizes, one for currents between 25 and 100 amperes with infinite gradation, and the other similarly for currents up to 200 amperes. The machine is supplied as a complete unit ready for connection to the supply main, and any ordinary flux-covered electrode can be employed.

Premier System.

The Premier system of arc welding aims at distributing the current at the required welding voltage without any mechanical control whatsoever. This is obtained by the use of a dynamo of a special type connected with the arc through a special reactance coil in the main circuit. This coil absorbs no appreciable energy, but effectively damps out any sudden rise in current, and at the same time helps momentarily to build up the current when any sudden reduction takes place.

The company manufacture plant of the multiple operator type which does away with large and wasteful series resistances.

A special type of plant for welding thin sheet metal has been developed. The machine consists of a very small transformer and choke coil, and sheets down to 18 gauge can be welded satisfactorily. Flexin welding tools and electrodes by means of which a flexible electrode is fed to the arc by means of a pneumatic or electrically driven hand tool represents a continuous welding system which ensures high welding speed and elimination of electrode waste.

Ferro-Arc System.

The Ferro-Arc system employs electrodes with a coating of flux and slag-forming materials. The core metal of Ferro-Arc electrodes is of the highest quality and made to an exact specification for arc welding. The principal component of the flux is powdered blue asbestos fibre specially treated and combined with other substances which control the melting point of the asbestos and enhance its power of dissolving oxides of iron and other impurities. Blue asbestos is peculiarly suitable for use as a flux, and it is doubtful whether any other material or combination can give such successful results in arc welding.

Ferro-Arc flux fuses evenly and level with the melting of the metal core, and when molten is fluid, free, and mobile, entirely covering and protecting the deposited metal. The flux has definite deoxidising properties which, together with its powerful solvent action for oxides, ensures the deposition of clean metal free from impurities. The scavenging action of the flux removes scale and rust from the surfaces to be welded, and so results in perfect fusion and interpenetration of weld and parent metals. The necessity for a substantial coating on the electrode for the achievement of best results should be emphasised. It is not possible to deposit sound metal free from oxides and impurities and which is thoroughly united to the parts to be welded without an adequate amount of flux and slag. A substantial coating in no way hinders the operator. On the contrary it assists him greatly, improving both the speed of deposition and ease of manipulation, while ensuring the soundness of the deposit and the neatness of finish. Valuable ingredients may be imparted to the weld from the coating.

The company manufactures three grades of electrodes for the welding of mild steel, *i.e.* Types A, B, and C, which vary in quality and price. The coating in each case is based on blue asbestos powder. There is also Type AA for the welding of mild steel, where exceptionally high strengths (about 30 tons per sq. in.) are required, or where it is necessary to hot forge the part after welding. As a recent development the *Ferro-Arc Welding Company* have undertaken the manufacture on an extensive scale of electrodes coated with blue asbestos yarn as distinct from powder. The uniform dependability and the consistent high quality of rods of this class are unrivalled for withstanding damage and deterioration both from rough usage in transit and from changing atmospheric and climatic conditions.

All the above types may be used on any standard plant using either direct or alternating current. Remarkably good results are obtained with these electrodes, the outstanding features of which are smoothness of working, penetration of the metal, neatness of finish, and high strength of the weld.

For those who require only a very lightly coated rod at a low price, the company provides its well-known ' Kathodes,' which give best results when connected to the negative pole of a direct current supply.

For the welding of cast iron two types of electrode are made. The standard type is specially designed to deposit a true cast iron in the weld, while Type D deposits a nickel-copper alloy which has the great advantage of forming a soft machinable deposit without preheating ; with this electrode cast iron may be welded ' in the cold ' without the formation of hard spots, particularly in the line of junction.

Electrodes to deposit 14 per cent. manganese steel and 0·5 per cent. and 0·8 per cent. carbon are also supplied.

A new development is an extremely successful electrode for welding stainless steel, particularly 'Staybrite.' This electrode deposits a metal containing approximately 8 per cent. nickel and

18 per cent. chromium. The composition of the electrode could be suitably altered so as to give other desired combinations of nickel and chromium. In working it is particularly smooth, fusion is perfect, and neatness of finish remarkable. The deposit is very tough and entirely free from blowholes. Its resistance to corrosion is as high as that of the metal on which it is deposited. It may be used for the welding of mild steel to stainless steel.

The Ferro-Arc Welding Company's system of electric arc welding employing Ferro-Arc electrodes has been tested and approved by Lloyds Register of Shipping.

A.C. System.

The A.C. welding system is one which embodies novel features. The nature of a welding arc is such that the use of bare wire with alternating current for welding purposes is impossible unless special provision is made to counteract the effect of the periodic cessation of power.

Before the introduction of the A.C. welding system, the use of alternating current for welding purposes was condemned as inferior to D.C., and was only used in conjunction with heavy slag-forming electrodes.

A paper which was read before the Institution of Welding Engineers* explained the theory of arc stability, and showed the difference between the A.C. welding system and the transformer and fixed reactance stabiliser, which had hitherto been in vogue. It also shows that the tendency of the arc to die out is counteracted by the method of arranging the choking effect in the circuit as a variable quantity instead of being a fixed value. The 'Alternarc' transformer of the A.C. system can be adjusted to have a certain average value for its reactance, and this governs the average value of the power supply to the arc, in the same way as a fixed reactance choke coil is designed to determine the value of the power supply to the arc. The reactance of the 'Alternarc' transformer, however, is not a fixed quantity, but varies with the current over the whole load cycle, in such a way that when the current is at minimum the reactance value is a minimum, and *vice versa*.

The effect of this method of arc control is to give very high arc stability; so high, in fact, that it is claimed possible to do equal, and even more efficient, welding work with alternating current than with direct current.

Alternating current has been condemned for welding on many occasions, owing to the fact that the arc stability factor supplied by the transformer and choke combination was so extremely low. This bad feature of poor arc stability has now been overcome by the A.C. system, and consequently, with maximum welding efficiency possible with alternating current, coupled with the desirable features of high electrical efficiency, portability, and low first cost, the A.C. welding system offers a most efficient and economical welding system.

The way in which the variable reactance control is arranged is as follows:—The 'Alternarc' transformer consists of a primary winding wound on one limb of a closed core, having two secondary windings, one of which is wound to have high mutual inductance and low leakage inductance with the primary coil, and giving a heavy leakage flux on full load. In some cases an alternative path is arranged for the leakage flux by extending the core yokes between which extensions a movable flux-diverter is arranged. Both sections of the primary windings are tapped at intervals to give adjustment to the voltage and also to the current, the movable flux-diverter giving a fine adjustment for accurate work.

The material used in the construction of the transformer is fireproof, the windings being composed of asbestos-covered wire, insulated with pure mica. Each of the larger type machines is provided with a cooling fan, and is enclosed in an oak case arranged with Sedan handles, in such a way that a whole apparatus is a portable unit.

To summarise, the claims made by the A.C. Welding Company for their system are—maximum welding efficiency, maximum arc stability (giving the choice of any electrode on the market); maximum electrical efficiency (giving minimum running cost); minimum upkeep (there being no adjustments of brushes, attention to commutators, etc.), and no maintenance charges. The machine is guaranteed against burning-out, and can only break down under wilful bad treatment.

The machines are normally supplied with an open circuit voltage ranging from 60 to 100, according to the settings of the secondary connections, but if required they are supplied with a standard 'Alternac' safety device, which limits the open circuit voltage to a maximum of 25 volts.

Electric arc cutting has been developed on the A.C. system. The system of cutting consists in the use of special cutting electrodes, which liberate free oxygen at the arc, steel being the basis of the electrodes on currents of 300 amperes, and carbon on currents from 600 to 1000 amperes.

Wilson Plastic-Arc System.

A wide and varied range of arc welding machines are manufactured on this system by *Messrs. G. D. Peters & Co., Ltd.* A special feature of all Wilson Plastic-Arc Welders is the Control Panel, which gives the machine welding qualities available in no other way. These panels, which have a range of adjustment to suit the particular welder, give close current regulation without the use of a separate exciter or brush moving. The whole equipment, which includes all accessories,

ELECTRODES

are manufactured in several grades to suit varying requirements, but each excels in its own type.

Blue Asbestos yarn coated electrodes of the highest quality, fully fluxed paste coated electrodes and lightly coated rods are all included in the Company's products.

Special electrodes for developing mechanical and hot forging properties in the weld are produced, as are also electrodes for welding Cast Iron, Manganese, Steel, Nickel-Chromium alloys, etc. etc

The Ferro-Arc System of Welding is approved by Lloyd's Register of Shipping.

is compact and built for service and can be supplied with a motor of practically any characteristics to suit the local source of power supply, or the generator can be supplied without a motor, to be driven by any means locally available, such as, for example, a belt. Alternately the unit can be petrol driven, and portable petrol sets are a speciality of the firm.

The electrodes supplied by the firm have a world-wide reputation and are known as the Wilson 'Colour-tipt' Welding Metals. The composition of each grade of metal, which covers all welding requirements, is the result of exhaustive experiments to provide an electrode having proper flowing qualities, penetration, and characteristics as deposited metal, to produce a sound, mechanical weld. The packing and marking of these electrodes has received considerable ingenuity and attention which ensures economy and their ready identification under practically all conditions of use. The welding plants and electrodes have the full approval of Lloyd's. The close current control, stability, and value is such that special alloys, such as the non-corrosive chrome alloys, can be welded without losing the effect of their essential elements in the weld.

Fluxode System.

The Fluxode system, Engineering Developments, Ltd., uses flux-covered and bare-wire electrodes which can be used with any arc welding plant. Mild steel, high carbon and manganese electrodes of both types suitable for high-class welding with high tensile strength or where a hard deposit, such as for reinforcing or building up tramway and railway rails, is required.

Arc welding plant to meet all conditions and for use on alternating or direct current has been designed from the point of view of economy and efficiency. The single operator set, for example, is suitable for any standard voltage on direct or alternating current supply varying from 100 to 500 volts. The set consists of an electric motor coupled to a specially wound welding generator which possesses a variable voltage characteristic similar to that obtained by the combination of a level voltage supply with a stabilising resistance in series with the arc.

Electric Blowpipe Welding.

In this process the electric blowpipe is essentially a horizontal-flame arc lamp using two carbons mounted like the letter V. The process was introduced by Dr. Zerener in 1890, and is usually known as the Zerener system. The flame of the arc was directed away or deflected downwards by means of an electro-magnet in series with the arc. The apparatus is bulky and complicated, and for even moderate-sized work it must be suspended from above. This method of welding eliminates the passage of the current through the work. It has not proved as successful as the methods already mentioned, and has been superseded by them. The Voltex Process is a variation of the Zerener method, in which the carbon electrodes are impregnated with metallic oxide which is vaporised by the flame of the arc.

Arc Welding Equipment.

Electric-arc welding may be done with a direct-current or alternating-current arc, having a reasonable degree of stability and sufficient amount of heat to accomplish fusion. The effect of the 'type' of current on the efficiency of metal deposition by the arc is threefold. It affects the speed of deposition, the amount of penetration or fusing of the metal, and arc stability. The design of the welding generator or transformer affects the cost of welding. The necessity for a special machine rests upon economic factors, and the differences between the various types used are those of power, cost of operation, and difference in speed of operation due to the relative stability of the arc.

The question of direct or alternating current raises many interesting points which have never been clearly determined. Good welding can be done with both direct and alternating current. Flux-covered electrodes are essential for certain types of alternating current machines, apparently because the lagging effect of the flux and slag maintains the necessary temperature during the periodical current reversals. Comparative data by independent authorities is missing, and the question of whether direct-current welding is faster or slower, whether flux-covered electrodes enable direct current to take the lead in welding speed, whether the practical losses in motor generator and resistance compare favourably or otherwise with the alternating-current system, etc., etc., are questions which are answered by contradictory claims by both parties to this controversy. However, there are advocates for both systems, and satisfactory equipment can be obtained for arc welding with direct or alternating current.

The successful application of arc welding is largely dependent upon the selection of the proper equipment. There are two systems in general use—(*a*) single operator system, where a separate machine is provided for each operator, each machine receiving its current supply from the supply circuit; (*b*) multiple operator system, where more than one operator receives current direct from the same machine, but each operator is provided with a control panel which enables him to vary the current without interfering with the other operators.

The equipment consists of a motor generator, control panel, and accessories. When using alternating current use is made of a transformer to reduce the distribution voltage to that suitable for the weld.

Amongst the accessories are protective equipment and electrode holders.

Protective Equipment.

The intense glare emitted in the process of arc welding consists of a combination of invisible infra-red rays, visible light rays, and invisible ultra-violet rays, and special safety devices are required to protect the operator from their harmful effects. For light electric welding it is necessary only to protect the eyes with goggles fitted with suitable coloured glasses. Hand shields are made for medium-weight electric welding work which can be done with one hand. They serve the double purpose of protecting the eyes of the operator and also shielding the face from the heat rays and ultra-violet radiations. For heavy electric welding it is common practice to use a helmet or hood which provides protection for the eyes, head, face, and neck, and leaves the hands free. With regard to the tint of the protective glasses, a reference to the note on goggles in the section on oxy-acetylene welding will be useful. The filtering glass used should cut off both ends of the spectrum, the ultra-violet and infra-red, and transmit, in reduced quantity, only rays of high visibility, such as the yellow and green radiations, thus giving the maximum visibility with the minimum reception of energy. For the protection of the hands and wrists leather gloves are used. These devices are subject to modifications to meet the requirements of special work. Neighbouring workmen and operators should be protected from the dangerous rays of the electric arc.

Precautions in Arc Welding.

The precautions that should be observed in arc welding have been set forth in a memorandum issued by the Factory Department of the Home Office (Form 329, June 1921). These deal with: (*a*) hand-screen; (*b*) helmet or mask; (*c*) gloves; (*d*) aprons; (*e*) protection from hot metal; (*f*) chipping of slag. The memorandum also deals with the comparative dangers of direct and alternating currents, use of direct current, injurious effects of radiations, etc. The memorandum on the Electricity Regulations (Form 928, 1925) should also be consulted.

Automatic Metallic Arc Welding.

Depositing metal using an automatic feed for the electrode results in a materially increased rate of deposition. Machines have been developed which are capable of welding steel 11 B.G. thick at the rate of 22 ins. per minute. This method of depositing metal is particularly advantageous on sections of uniform shape upon which a considerable amount of metal is to be deposited. Automatic welding does not eliminate the human element in welding, but does in certain cases greatly increase the speed of the process, and in other cases obtains results which are beyond the limitations of manual operation. Automatic welding with the bare metallic electrode is in more general use at present than any other method. In one type of machine the electrode is fed to the arc from a reel by means of feed rolls actuated by a 30-volt motor which is shunted across the arc when the arc is struck. Regulation of feed is maintained by two contractors which change the direction of rotation of the feed motor when the arc voltage increases or decreases above or below a certain amount. Research has proved conclusively that a faster, stronger, and more homogeneous weld can be made on material $\frac{1}{8}$ in. or more in thickness by use of a multiple arc automatic welder, depositing the metal in two or more layers, using about 350 amperes in each arc, rather than by depositing in one layer, using an excessively high amperage. A number of welding applications involve all the requirements of automatic welding except that the size or weight of the pieces to be welded prohibits convenient handling, clamping, and traversing. In such cases a semi-automatic welding machine has proved to be of great advantage. One type of machine feeds the welding wire through a flexible conduit to a welding nozzle in which the control switch for the feed motor is located. The control mechanism operates to start and stop the feed motor. The maintenance of a uniform and steady arc depends on the operator.

Arc Welding Applications.

The application of arc welding to repair and manufacturing, particularly for the replacement of castings, is very extensive, but its application should be made with a full knowledge of the possibilities and limitations of the process. In the welding of iron and steel, with their great variety of physical properties, a familiarity with the wide range of conditions is necessary to meet and solve the problems presented. In welding cast iron, copper, brass, aluminium, etc., the application of arc welding should be looked upon as in the development stage, where welds with physical, chemical, and mechanical properties similar to the base metal are required.

A complete investigation into the welding of cast iron is being made, and the results, as far as they have gone, demonstrate that it is possible to weld some grades of cast iron if the proper method and conditions of welding are obtained. The following points have been considered :—(1) preparation of the parts; (2) prevention of slag inclusions; (3) suitable values of current; (4) method of deposition and its effect on the strength and hardness of the weld; (5) reversed polarity versus straight polarity; (6) effect of long versus short arc; (7) effect of speed on the softness of the weld; (8) the hard zone and its removal; (9) relative weldability of various grades of cast iron; (10) tests of electrodes.

Cost of Arc Welding.

The cost of electric arc welding with the metal electrode process depends upon several variable factors, such as: (1) the price of labour; (2) the characteristics of the arc, (*a*) arc easy to maintain, (*b*) arc difficult to maintain, (*c*) amount of heat available; (3) the cost of power; (4) the cost of electrodes; (5) supervision required, (*a*) production work, (*b*) work of a varied character; (6) interest charge on equipment.

Welding speed is fundamentally dependent upon the rate of metal deposition. This rate varies with such factors as, energy required for liquefaction of electrode material, arc stability, current density, and electrical resistance of electrode material. It has been shown that high current welding results in an increase of 100 per cent. in the speed of welding a butt joint. Butt joints in ¼-inch plate may be welded at a maximum rate of 5·3 ft. per hour when employing 175 amperes; at 10 ft. (or more) per hour when using 400 amperes.

RESISTANCE WELDING.

There is a marked distinction between the joining of metals by the two electric processes, viz., arc welding and resistance welding. In the former the heat is localised through the action of the electric arc and no pressure is applied; in the latter the heat is localised by the resistance to the flow of the current and pressure is used.

The process of resistance welding is based upon the phenomenon that a poor conductor of electric current will heat if current is forced through it, or that a good conductor will also heat if enough current is passed through it. Since an imperfect joint, such as the abutting ends of two pieces of metal, or the lapping of two pieces of metal which are to be welded, is a poor conductor and offers great resistance to the passage of the current, it will naturally heat and finally cause the metal to fuse and flow sufficiently to weld. In practice the operation is very rapid because comparatively large amounts of current are used.

For this type of welding a single-phase alternating current of any commercial frequency is used. The transformer in the machine will take the current from an ordinary shop circuit and reduce it to a suitable welding current.

Resistance welding is only suitable for duplicate or repetition work. In general one machine is designed for handling pieces of the same metal and for making joints of similar design. Repair jobs have been done in special cases, but it is only in rare cases that such an adaptation is attempted.

A resistance welding machine is simply a single-phase transformer having a secondary of one or two turns, the voltage required between the terminals being only five to ten volts, and the current being limited only by the size of the pieces to be handled. The transformer is built into a heavy frame which supports the clamping jaws to handle the work and mechanical devices to regulate the heat and pressure. The machine has reached a high degree of perfection, and large savings of time and labour have resulted in production work. The principle involved has been applied in the construction of a variety of machines.

By some one of the resistance welding processes, nearly all metals and alloys can now be welded. Tin is the notable exception. The cross-section of stock that it is possible to weld by the resistance process now seems to be limited only by the electric power available. Special adaptations for heating rods, bars, billets, rivets, etc., and electric brazing and soldering machines are available. Special machines for zinc tube welding, automatic spot welding, rivet heating, forging hearths, welding hollow articles, etc., etc., have been designed, and their main features have been dealt with in a paper read before the Institution of Welding Engineers.*

* 'Resistance Welding,' by F. E. Saunders, M.I.E.E.

Butt Welding.

Electric butt welding consists in joining pieces end to end by securing complete fusion of the entire cross-section of the pieces. The pieces to be welded are placed in the clamping jaws, one of which is stationary and the other movable; enough pressure is exerted to bring the ends into contact and the current is then turned on. As soon as the welding temperature is reached the operator increases the pressure, thus forcing the pieces together, and turns off the current. Nearly all metals used commercially have been welded by this process.

Butt welding may be subdivided into three classes, namely, (1) upset welding, (2) flash welding, and (3) contact flash welding or automatic butt welding.

As regards the first subdivision, in which the weld is made by butting the cold ends of the stock to be welded and then applying the electric pressure, it is apparently being superseded for most purposes by flash welding.

Flash welding is made by applying the current before the ends are in actual contact and utilising the flash or minute arcs that play between the ends of the stock. Some advantages of flash over upset welding are (*a*) less power required, (*b*) less extrusion or upsetting, (*c*) burnt metal is thrown off, (*d*) increased production, (*e*) stronger welds. The best technique for the flash welding of tungsten steel tips to medium carbon steel shanks in the manufacture of machine cutting tools, and the serviceability of such tools as indicated by bending and service tests, has been determined.

The third subdivision, contact flash welding, is in some respects similar to percussive welding. The weld is made almost instantly by using high continuous contact pressure and heavy current, the current being cut off by automatic methods of control.

Spot Welding.

Electric spot welding consists in pressing the pieces together while passing the current through them, and localising the flow of the current so that the weld is confined to 'spots' between the electrodes, which are used to secure the pressure. The term automatic spot weld is given to a spot weld made on a welder which applies the pressure, makes and breaks the circuit all automatically.

The material to be welded is placed between copper die points supported on the ends of two arms, and the points are brought firmly together on the metal by the use of either foot or motive power. The current is then turned on. The metal, being a poor conductor, becomes heated, and when heated to a sufficient degree, pressure is applied. In the case of automatic control, the current is turned on and off and the necessary welding pressure applied automatically by controlling mechanism usually driven by a variable-speed motor. The majority of commercial metals can be spot welded, but it is essential that the metal to be welded should offer a considerable resistance to the electric current, otherwise sufficient heat cannot be generated. The technique for spot welding galvanised iron has been determined and gives very satisfactory results. The requirements for successful welds are rounded die points and twice the current and half the pressure required for ungalvanised metal of the same thickness. The spot welding of light materials guarantees a successful product and increased production. A commercial spot welder for ¼-inch plates is in use.

During the past few years considerable investigation has been carried out with regard to heavy spot welding for ships and constructional work. Large machines capable of supplying a welding current up to 100,000 amperes, and equipped to exert a pressure up to 30,000 lbs. per square inch on each spot, have been constructed. The main difficulties which have been encountered are, briefly, electrode-tip protection and the preparation of the materials to be welded. Two secondary considerations have been the separation of the electrodes and the shape of the head of the spot welder.

The following indicate the variations of spot welding:—

Button and Disc-Depression Welding.

Where very thick work is to be spot welded it is often desirable to find means to localise the current and cut down the amount of pressure required. Small metal discs or buttons can be used for this purpose placed between the head of the welder and the metal to be welded. Disc-depression welding differs from button welding in that in the disc-depression method an annular depression is provided in one of the sheets, around the disc. The method makes possible the use of a comparatively light machine for welding heavy steel plate, and also the use of less power and time for making the welds.

Bridge Welding.

This method is used to join thin sheets edge to edge without overlapping and without reducing the dimensions of the pieces. The sheets are brought together in their correct position, and then thin strips or discs are spot welded across the joint.

Multiple Electrode Welding.

Time and power can frequently be saved by making several welds at once, in which case the spot welder is equipped with two or more electrodes. It is advisable to have projections on one of the pieces to be welded to assist in localising the current. Successful multiple welding requires a separate transformer for each weld.

T Spot Welding.

When pieces are welded in the form of a T by holding one piece in a hollow electrode and welding it to the other the resulting weld is called a T spot weld.

Point or Projection Welding.

In this method the metal to be welded is provided with points or projections. The points are brought in line with each other, and the welding effect is to provide a smaller contact point which increases the resistance and allows the weld to be made with the consumption of less time and power. Ridge welding is the same as point welding, except that, instead of a single point, a ridge is raised in the metals in such a way that the ridges on the two pieces come together in the form of a cross.

Duplex Spot Welding.

In this type of spot welding two transformers are used simultaneously on opposite sides of the sheets to be welded and their currents pass through two secondaries, welding two spots simultaneously.

Combinations of all the above processes have been made for special jobs. Sometimes it is only necessary to make a change in the construction of the electrodes to make a machine do work of a varied character.

Seam or Line Welding.

This process practically combines the features of butt welding and spot welding, and is used for joining pieces along a continuous line or seam, usually by moving the joint in the path of the current, so that fusion is secured continuously. Machinery has been developed, but is usually limited to work on light stock and short seams. A recent development is the use of interrupted current for making longer seams on heavier stock. Excellent welds have been obtained by the step-by-step method in which the roll moves and stops alternately. During the rest period the rolls are energised and the welds made. The speed of welding is rather slow. The construction of all-steel motor bodies has given rise to a development which can be classified as flash seam welding, and consists of flash welding a long seam in a machine which really consists of two butt welding machines mounted on a single base. A 56-in. seam is flash welded in approximately 5 seconds. Standard seam welders are usually equipped with two electrodes, one connected to the work and the other a roller running over the seam, or both electrodes may be converging rollers, with the converging edges resting on opposite parts of the work near the edge to be welded. The work is passed beneath the rollers, which carry the current into the metal, and makes a continuous line of welding. The work must be carefully cleaned and be securely held by the machine to get good results. The width and strength of the weld depend upon the current, pressure, and speed adjustments as well as upon the size and character of the electrodes and the shape, size, and character of the metal being welded.

Considerable development work has been done during the past two years. It has been applied to the manufacture of steel barrels, casks, tanks, ventilators, heating and ventilating pipes, etc. Seams can be made at a rate of 40 ft. per minute on $\frac{1}{16}$ in. sheets, and 20 ft. per minute on $\frac{1}{4}$ in. sheets. The welds may be butt, lap, or bridge, and be made continuously or progressively.

Mash Welding.

Mash welding is a process of welding rods, wires, strips, etc., by crossing or overlapping the pieces and welding between relatively large electrode surfaces under pressure. The process is used in the manufacture of lamp-shade frames, wire waste baskets, etc.

Electro-percussive Welding.

This is a process which is chiefly intended for manufacturing applications in which large quantities of duplicate parts are to be produced. The underlying principles utilised in percussive welding were discovered in 1905 by Mr. J. Chubb, of the Westinghouse Company. Following his original experiments, machines were developed for welding metals in wire form of rather small cross-section. Widely different physical properties offered no obstacle, and

ductile welds can be made with copper and aluminium, platinum and lead. Electrical devices are used whereby a rapid small separation of the parts to be welded causes an intense arc to melt the surfaces. At the proper moment a forging hammer forges the pieces together. The advantages claimed for the processes are (*a*) power saved ; (*b*) time of welding negligible ; (*c*) welds of unequal sections are possible ; (*d*) welds of unlike metals can be made ; (*e*) uniform welds; (*f*) cost of finishing welds reduced. Recent results have shown that percussive welding has many valuable applications, especially in non-ferrous and steel-alloy welding.

Experimental work has been directed toward extension of the process to larger cross-sections. A large impulse transformer has been built capable of storing 20,000 joules. Sections up to ¾ in. diameter have been successfully welded and no apparent limitations are anticipated from a process point of view.

ELECTRIC CUTTING.

Although cutting with a blowpipe has many advantages over electric arc cutting, yet there are many places where the electric arc can be used advantageously. The groove is not so narrow as that cut with a blowpipe, nor is the surface cut as clean. One advantage of cutting with the arc is that scale, either on the surface or in pockets, cold shuts, sand pockets, and blowholes have no appreciable affect on the cut and will not extinguish the flame or arc as is the case of oxy-acetylene cutting.

The electric arc will cut any metal, ferrous or non-ferrous, and has been found particularly useful for the cutting of cast iron. The thickness that can be economically cut by the arc varies from 4 to 6 inches, for straight cutting. The current necessary for cutting operations on general and heavy cutting varies from 800 to 1,200 amperes. The voltage of the cutting arc varies between 25 and 45, a good average being 37. The best arc for cutting is a reasonably long one or a reasonably short one, whichever is preferred. The chief point is to have the liberation of energy near the work to be cut.

It will be seen that heavy values of current are required, and special apparatus has been designed so that the arc could be controlled with these heavy currents. An important part of these developments is the design of a handle to protect the operator, hold the electrode, and to carry 1,000 amperes. A small item like the use of pure graphite instead of carbon for electrodes means the difference between success and failure.

Increase of current means larger electrodes and hence more metal to be cut out. The latest development for this work is a low resistance graphite electrode and the approximate sizes for various current densities are as follows :—200 amperes, ¼ to ⅜ in. electrodes ; 300 to 400 amperes, ⅜ to ½ in. electrodes ; 400 to 600 amperes, ½ to ⅝ in. ; 600 to 800 amperes, ⅝ to ¾ in ; 800 to 1,200 amperes, ⅞ to 1 in. electrodes.

Cutting on heavy sections is generally best accomplished from the underneath side or from a vertical face tipped slightly greater than 90 degrees so that the molten metal can flow away, although the action is not entirely simply melting metal. In cutting with the arc a reasonably smooth surface can be obtained by paying attention to one side only, or the cut may be made rough and trimmed up smooth by a second application of the arc.

Recent developments consist of a special electrode for cutting with the arc, and for such work as piercing holes. This special electrode, covered with a coating giving off free oxygen under the temperature of the arc, gasifies the entire metal melted, so that the boring action is uninterrupted after once started. This electrode is used by starting the arc and immediately pushing the electrode into the puddle. After the hole is through the piece it can be widened to any size or shape by drawing the arc around its edges. This type of electrode only takes from 250 to 350 amperes. A development in under-water cutting is an adaptation of the carbon electrode arc cutting process, in which the carbon electrode is pierced by two small brass tubes, through which a special cutting gas is supplied from the surface. The gas oxidises and blows away the metal melted by the arc, and also converts the surrounding water into steam, thus making a gaseous envelope for the arc. The combined action serves to greatly speed up the operation of the cutting electrode, as the metal is blown aside before it has a chance to solidify. This device has been used successfully for cutting metal between three and four inches thick at a depth of about 70 ft.

ATOMIC HYDROGEN WELDING.

Equipment is now available for atomic hydrogen welding. The process consists in passing a stream of hydrogen gas through the arc formed between two electrodes. The heat of the arc breaks up the hydrogen molecules into atoms, and these combine again a short distance beyond the arc, and in so doing liberate a large amount of heat. Since atomic hydrogen is a powerful reducing agent, it reduces any oxides which may form on the surface of the metal, and metals can be melted without the slightest trace of oxidation.

The equipment represents the results of continuous experiment, research, and trials over a considerable period. The outfit consists of a single-phase transformer for converting the voltage of a 60-cycle supply to one suitable for the welding equipment, a specially designed variable reactor for providing the proper welding current and voltage, and a welding blowpipe by means of which the actual work of welding is performed.

The blowpipe consists of a holder supporting two tungsten wire electrodes, the electric conductors connecting these to the reactor, and the tubing for the hydrogen gas. Each electrode is supported inside a nozzle through which the hydrogen is forced out around the electrode. The combination of electrodes and nozzles is set at an angle, and the distance between the electrodes, or arc length, and also the flow of gas, are readily adjustable. In contrast to the usual method of arc welding, there is no current flowing from the electrodes to the work to be welded ; the circuit is completed from one electrode to the other. When welding ceases, the welding circuit is automatically interrupted until the operator is ready to weld again, when the circuit is automatically restored

In making welds the metal is melted under the heat of the arc, but to add additional metal a welding wire or rod must be used and fed into the arc in much the same way as that followed in oxy-acetylene welding.

The reactor consists of a U-shaped core provided between with pole faces, between which a pivoted armature can move. The legs of the core are provided with coils connected in series with the electrodes of the blowpipe. The amount of welding current and voltage is governed by the movable armature which changes the air gap of the magnetic circuit and therefore the reactance.

The equipment is made for operating from 60-cycle, single-phase circuits, and for use on ordinary metals less than ½ in. in thickness, or on hitherto unweldable metals of greater thickness. Extremely thin material can be welded. The process is particularly adaptable to the welding of metals and alloys so far not weldable by other methods.

THERMIT WELDING.

Thermit is a trade name for a mixture of finely divided aluminium and iron oxide, which when ignited reacts to produce a superheated liquid steel at 5000° F. The underlying principle of the process is the high chemical affinity of aluminium for oxygen. Up to a temperature of 2800° F. thermit is an inert mixture. At that temperature the aluminium unites with the oxygen of the iron oxide and comes down as liquid steel at about twice the temperature of ordinary molten steel. If steel at this high temperature is poured around the sections to be united, especially if the sections have previously been preheated, it will melt them and amalgamate with them so as to form a fusion weld.

Four varieties of thermit are produced for welding ferrous material, *i.e.* plain, cast iron, railroad, and wabbler thermit.

In making a thermit weld, the parts to be united are first lined up with a space between the ends, the extent of which depends upon the size of the sections to be welded. The ends are thoroughly cleaned and a wax pattern is formed around them, the exact shape of the reinforcement of thermit steel which is to be cast at that point to make the weld. A sand box is next rammed around the pattern and inside a sheet iron box, provision being made for pouring gates, heating gates, and risers. The parts to be united are brought to a good red heat by suitable means, such as compressed air liquid fuel. The charge of thermit is placed in a conical shaped crucible supported over the pouring gate of the mould and ignited by means of an ignition powder. In 25 to 35 seconds the reaction is completed and the crucible tapped. The slag does not enter the mould.

The process is extensively employed for locomotive repairs, marine repairs, crankshaft repairs, steel mill repairs, pipe welding, rail welding, and miscellaneous heavy welding. Detailed instructions are available for carrying out thermit welds in the fields mentioned. The process is adapted to all sizes and weights of pipe up to 6 in. diam., and an important feature possessed by the thermit pipe welding process is the ease with which it can be applied to the welding of coils. The joints can be welded either before or after the pipes are bent.

ADDENDUM.

The following is a brief review of welding progress in 1930:

In spite of the stagnation in practically every branch of engineering the demand for welding equipment has increased. Arc-welding has made marked progress, particularly for the welding of steel structures and 'redesign engineering,' in which castings, such as frames of machines, are replaced by welded steel construction. Considerable improvements have been made in resistance welding machinery, and projection welders have been built that require over 3000 KVA power to operate them. The bronze welding of cast iron, etc., is now extensively employed.

The use of automatic arc and oxy-acetylene welding of several different forms has increased. An improved portable semi-automatic arc-welding equipment suitable for use with either the open or hydrogen-shielded arc has been perfected. The atomic hydrogen process was further extended in usefulness by its adaptation to automatic welding. This permits of greater speeds with higher currents than were feasible with the hand operation of the process. Several new types of arc-welding machines have been designed to give the welding circuit of single-operator machines greater stability.

SECTION XLI

EXPLOSIVES.

(Contributed by Professor W. R. Hodgkinson, F.R.S. (Edin.), Ph.D., F.I.C., C.B.E.)

Explosives may be classified into 'Propellants,' which are required to produce a rapid but steady rise in pressure in some kind of firearm; others may be termed 'Detonators,' or the less definite term 'High Explosive.' The latter are practically instantaneous in action and produce a wave or vibration of high velocity. Under certain conditions some substances may behave as belonging to either class.

The first propellant, 'Black Powder,' has since 1770 (about) consisted of nitre 75 per cent., charcoal 15 per cent., and sulphur 10 per cent. Practically all the gases, which may be 700 times the volume of the powder, arise from the nitre, the volume varying according to the density of the powder and to the conditions at burning.

Gunpowders do not detonate, but may give a very rapid rise of pressure if burnt in a closed space. Being porous, though dense, the first formed and very hot gases are driven through the remainder of the charge, igniting it *en masse*.

Cordite.

Cordites and the like are practically the most satisfactory propellants invented; owing to their gelatine-like structure they are non-pervious to gases. All true colloids show this property in some degree; the rate of burning can therefore be well regulated by the area of surface, volume of gas, and temperature. Owing to their composition, these explosives are practically smokeless. The cold-gas volume (i.e. volume at ordinary temperature) is in the region of 1,000 times that of the powder, and the temperature seldom less than 2,000° C., and may be above 3,000° C., according to composition. 'Cordite' proper consists of gelatinised high grade gun-cotton with a certain amount of nitroglycerine and a mineral jelly incorporated while the gelatinising agent is still present, the agent eventually drying off. A number of varieties of these powders are made with lower grades of gun-cotton, their physical properties being much the same. These powders are not easily detonated and are useless for blasting purposes.

Gun-cotton.

Gun-cotton' and 'Cellulose Nitrates' are made by the action of a cool mixture of nitric and sulphuric acids on cleaned cotton waste or the like. Strength of acids, temperature, and time of contact determine the extent and nature of nitration. Real gun-cotton contains about 13·8 per cent. of nitrogen, nearly corresponding to $C_6H_7O_2(NO_3)_3$.

Varieties of nitrated cellulose containing 10 to 11 per cent., or less, nitric-nitrogen than real gun-cotton are also used in some classes of propellants.

Gun-cotton is unaffected by water and does not burn if containing about 10 per cent. of moisture. When dry it ignites at between 160° and 180° C. It burns without smoke and is easily detonated by a sharp blow on a hard surface. When wet it can only be detonated by a primer of dry gun-cotton. When pulped and pressed into slabs, gun-cotton (13·8 per cent. N.) is used for blasting; its action is very local.

Nitroglycerine.

Nitroglycerine is formed by the action of mixed nitric and sulphuric acids on glycerine at a low temperature. It is a colourless oily liquid of sp. gr. 1·6. It freezes easily, and melts at 4° C. It is practically insoluble in, and unaffected by, water. Solid or liquid, it is easily detonated by percussion or by heating to about 150° C., hence the danger of thawing the solid nitroglycerine. As a liquid it is unpractical as an explosive, but when mechanically absorbed into a porous inert material, or incorporated in the substance of a jelly, useful preparations result.

Dynamite.

'Dynamites' which fulfil most of the requirements for blasting, and are reasonably safe, consist of nitroglycerine incorporated in kieselguhr, cork charcoal, and the like non-gritty powders. Generally some metallic nitrate, colouring or binding dope is added. Dynamites can be detonated by fulminate detonators. They are comparatively safe to handle and store for a moderate time in a place of medium temperature. Water may cause the extrusion of nitroglycerine from most forms of dynamite.

Gelignite.

'Gelignites' are mainly a thin jelly of a low grade gun-cotton in nitroglycerine; warm nitroglycerine is usually the gelatinising agent, but others may be employed. They may contain about 90 per cent. nitroglycerine. They are plastic, waterproof, and more powerful and convenient than ordinary dynamites. They should be stored in a place of cool even temperature. Most of the gelignites are doped, for some real or imaginary object.

Permitted Explosives.

'Permitted Explosives' for use in mines are such that comply more or less perfectly to certain tests, such as non-ignition of fire damp or coal dust, not producing a dangerous amount of poisonous fumes, considerable range of safety in storage and use. In many of these explosives, ammonia nitrate is the main oxygen carrier, the combustibles being benzene derivatives such as nitrobenzene, nitronaphthalene, and the like, with or without wood meal or inert powders to cool the flash.

Perchlorate of ammonia is the chief active material in some blasting compositions for civil or military use (cheddites). They are useful in fiery mines, as a quantity of hydrochloric acid gas is produced on explosion which acts as a damper of flame. Almost any kind of organic matters may be used in this class. Paraffin wax is often used, as, amongst other properties, it is waterproof.

Perchlorate compositions are stable and keep well, but all are liable to explode on moderately strong percussion. Generally they simply burn violently on ignition by a flame.

Ordinary chlorate compositions should be completely barred, as they are never safe and are erratic in use.

Detonators.

Detonators are substances employed to start the disruptive explosion or detonation of other compounds which alone may not explode by a flame or a moderately hard blow. Owing to the extreme rapidity of their explosion, detonators initiate a molecular decomposition of the main explosive, or it responds to the wave blow of the detonator.

Mercury fulminate, $HgN_2C_2O_2$, is the oldest and most commonly used detonator. It may be used alone or diluted with nitre, antimony sulphide, potassium chlorate, or even inert substances in some proportion, in order to regulate its sensitiveness, or reduce or modify the manner of exploding.

Cap and igniting compositions contain same proportion of $KNO_3Sb_2S_3$ and $KClO_3$.

Small quantities of fulminate, say 2 grams, may flash off if fired open, but the flimsiest cover will cause it to detonate on firing by a flame contact. A very slight suddenly applied pressure causes detonation. Its function in cap compositions is to respond to the blow of the hammer and ignite the other ingredients.

Lead azide, PbN_6, acts similarly to fulminate, is stronger and quicker in action, but probably not so amenable to regulation as fulminate.

Fuses.

These are, generally, some arrangement for firing an explosive at a desired moment. They consist, as a rule, of finely ground black powder contained in a paper tube protected by tape, machine-wound over it and waterproofed by some resinous or pitchy composition. Rate of burning may be controlled by fineness of powder, and in some cases by its composition, diameter of tube, etc.

In military fuses the powder has to burn along a circuitous route of determinable length in a metal container.

Fuses for blasting are packed in barrels and cases containing 300 or 500 coils of 24 ft. length. The average rate of burning of safety fuses is 75 to 90 secs. per yard. (See also 'Trinitrotoluene.') The fuse end is inserted in the detonator cap, which is then secured in proper contact with the explosive cartridge or charge, which may be tamped in the bore hole or not according to nature of explosive. (See also 'Blasting,' page 2572.)

Lyddite, or Picric Acid.

Lyddite, or picric acid, $C_6H_2OH(NO_2)_3$, is mainly a military explosive. It is somewhat difficult to detonate, otherwise there is no reason against its use for rock blasting. When some quantity is burnt there is a liability for it to pass into the detonation stage. The chief danger in connection with it is the liability to form metallic compounds (picrates), which are extremely sensitive to heat, friction, or percussion. There are several related substances with similar properties and uses, such as dinitrophenol, nitrocresols, etc.

Trinitrotoluene.

Trinitrotoluene (T.N.T.) and trinitroxylene (and other stages of nitration of toluene, xylene, etc.) are mainly military explosives, but T.N.T. has been used for some time in instantaneous fuses for civil work. Under proper conditions all these substances could be used for blasting.

Amatols.

Amatols (of various catagories) are essentially ammonia nitrate compositions with T.N.T. and similar substances. The violence of their explosion is increased by the addition of small quantities of powdered aluminium, magnesium, and other substances.

Amatols have a great future as blasting agents, but some of them are very sensitive and are not quite waterproof.

Blasting Machines.

Dynamo Electrical Blasting Machines are specially built to explode all blasting charges with absolute safety, either in stone quarries, coal mines, or oil shale workings. Being water and damp proof they are always ready for action.

SECTION XLII

PAINTING — VARNISHES — METAL LACQUERS AND BRONZES — LUBRICANTS AND OILS — CLEANING-COMPOSITIONS — MISCELLANEOUS.

(*All Parts by Weight unless otherwise Specified.*)

PAINTING.

Painting Woodwork.

A mixture of linseed oil and white lead is the best preservative of wood. The linseed is the preservative; the white lead gives body and opacity. Spirits of turpentine is added as a solvent, to enable the paint to penetrate into the pores of the material; the solvent should be light and easily evaporated.

Boiled linseed oil dries quicker than raw, but is darker and thicker than the latter.

To Remove Oil Paint.

2 lbs. washing soda, 2 lbs. quicklime, mixed to consistence of cream, spread on, and kept moist for an hour. The paint can then be washed off.

Glazier's Putty.

Whiting and raw linseed oil, well beaten up.

To Remove Old Putty.

Paint it with nitric or hydrochloric acid, and after about an hour it will be soft enough to remove; or a hot iron will soften it at once.

Painting.

In painting woodwork for the first time, kill knots with coating of fresh slaked lime; then in 24 hours scrape off, and paint knots with mixture of red and white lead and linseed oil; or use red-lead powder mixed with strong glue-size, and apply warm—the work can then be gone on with in a few minutes; when dry, smooth with pumice stone. Next put on priming coat. All holes are then stopped with glazier's putty, and the required coats added; each coat in good work is rubbed smooth with glass-paper before adding another.

Painting required to have no gloss has an additional coat, made with turpentine only, and no oil, called a *flatting coat*.

For old work, if much soiled, wash with soap and water and scour; if foul with smoke and grease, wash with lime and water; then commence with *second* coat.

New woodwork should have 4 coats; for periodical repainting 2 are sufficient.

Priming.

This generally consists of a mixture of white lead and red lead, irrespective of the colour to be used in finishing. The lead mixture is diluted with boiled linseed oil and a small quantity of turpentine. A special asbestos priming for painting fibro cement and all classes of asbestos sheeting is supplied by *Messrs. Walter Carson & Sons*, Grove Works, Battersea, London, S.W. 11.

'Muraprime.'

'Muraprime' (*Walter Carson & Sons*) fills a long-felt want for a decorative and reliable weatherproofing paint for rough cast, cement and stucco work. It is specially recommended for porous plaster, brick and cement surfaces, rendering them damp-proof and ensuring dry inside walls. As an undercoating where it is proposed to use paint, enamel or paper, 'Muraprime' is invaluable owing to its property of holding back stains and resisting damp. It is made in white, cream, yellow, green, and pink; other colours are supplied to order.

'COVERINE.'

This paint (*Walter Carson & Sons*, Grove Works, Battersea, London, S.W. 11) is a white undercoating, which saves time in the preparation of undercoats. It is ready for use in five minutes, and requires to be thinned with turpentine only. One coat is equal to two coats of white lead paint, and is consequently a saving of time and material. It dries hard, and can be coated in a few hours. The finishing coat can be applied and the work completed in one day. It forms a good undercoating for gilding, and will stand washing.

'MURALINE.'

This is a washable water paint (*Walter Carson & Sons*), and is sold in dry powder, in forty artistic shades. Water added to the powder in an equal proportion makes a sanitary washable paint, which forms a highly perfect and durable surface. Compared with paste distempers (which contain about one-third of water), it is claimed to effect a considerable saving, owing to its great covering power. 1 cwt. covers 600 to 700 square yards on non-porous surfaces. It will never deteriorate if stocked in a dry place, unexposed to the air. 1 cwt. of powder with 1 cwt. of water makes 2 cwt. of paint. It can be applied to new lime plaster, if dry, without injury to the colours. It works and flows evenly under the brush, and leaves a hard, smooth surface. Intermediate shades may be produced by mixing colours or by reducing with white. It is non-poisonous and an excellent disinfectant. The colours are fast to light, and do not discolour. It does not rub off, scale, or flake. The white is an excellent covering for ceilings. Unlike whitewash, removal is unnecessary before repainting if in sound condition.

Painting Ironwork.

For new ironwork, 3 coats Torbay or other oxide of iron paint answers well; 1 lb. mixed with oil will cover from 8 to 12 yards. For periodical painting, 2 coats. For the first, or first and second coats on iron, red lead is very generally used; 1 lb. mixed with oil will cover about 5½ yards.

'FERRI-SILICON.'

This paint (*Walter Carson & Sons*), which can be made in any colour, is a cheap and durable preservative for ironwork, woodwork, and all exposed surfaces. It is a combination of iron and other oxides with silicates, which, when incorporated with a special enamel oil, produces a paint closely resembling enamel, but with a very tough and elastic surface, absolutely impenetrable. The manufacturing process which the enamel oil undergoes is claimed to render it at least twice as durable as the finest linseed oil. The paint is specially suitable for use on gasometers, as the colours are not affected by contact with sulphuretted hydrogen gas, sulphide of ammonia, etc.

'ANTI-CORROSION.'

This paint (*Walter Carson & Sons*) is for out-door work as a preservative for iron, wood, stone, brick, compo, etc. It is employed by many of the leading railways both at home and abroad, and also on life-boat stations. It is well adapted for coating the roofs of corrugated iron buildings, etc., and is especially recommended for buildings exposed to the corrosive action of sea air as it does not blister and wash off under these trying conditions.

SYRONITE ANTI-RUST PAINT.

Syronite is a thin transparent syrup which can be painted upon new ironwork before, during, or after erection, or upon existing structures that are already rusting. If the structure is in a bad state before the Syronite treatment is undertaken, the surface is first well brushed with a stiff wire brush to remove all loose rust. A coat of Syronite is then applied, its action being to penetrate through any remaining rust and cause this to shed off. When shedding has taken place, another coat is applied, and then the treatment is complete.

Pigments can be combined with Syronite when required.

A peculiar feature of the material is its capacity of 'creeping' or spreading. Ordinary paint stays exactly where the brush leaves it, and as the brush cannot always get under and along joints, round rivets, etc., these parts do not get equal protection with the general surface.

Preservative for Ironwork.

(1.)

Coal-tar boiled till the watery vapour and naphtha are expelled, and mixed when cold with ½ pint of naphtha and the same amount of boiled oil to each gallon of tar.

(2.)

Experiments carried out by the Military Engineering Department at Brest have shown that as an effective preservative for metal work coal tar is rendered far more efficient by the addition of a small quantity of quicklime, in the proportion of one part of lime to two parts of tar. The mixture, after being heated to the boiling point, is brushed upon the ironwork at a temperature of about 120° F. The tar should be used over a coating of red lead.

(3.)

A valuable rust-inhibitive coating for general priming or finishing work may be prepared from sublimed blue lead. Two parts of blue lead and one part of linseed oil containing about 5 per cent. of turpentine drier make a paint of the right consistency. When this paint is used for top-coat work in marine exposures—battleship gray—the addition of 1 per cent. of carbon black to the blue lead aids in the maintenance of the colour.

Rust-proof Coating for Iron or Steel.

Linseed oil, 25 parts; calcium resinate, 36 parts; manganese borate, ½ part; lead acetate, 1 part; naphtha, 37½ parts; artificial graphite, 25 parts. These are mixed and applied to the metal by brushing, or dipping, or any other method. The article is then baked at 300° F. for 1 hour and 40 minutes. The coating is highly lustrous and resistant to corrosion.—*American Machinist.*

Note on Ironwork Painting.

According to experiments published in the *Bulletin de la Société des Ingenieurs Civils de France*, a number of coats of paint form a much less effective rust preventive for metal than a single layer does. Iron plates well cleaned and polished were coated, some with one coat and some with two, three, or more coats of paint, and then exposed to the action of steam for a whole day, after which the paint was removed and the plates were examined. The first was as bright as it was before exposure to steam, the second showed a few rust spots, the third was still more attacked, and the fourth entirely so. This result is stated to be due to the fact that the deeper layers dry badly and tend to dissolve the uppermost coating, increasing its porosity to air and moistare.

Painting Zinc.

Dissolve 1 part chloride of copper, 1 nitrate of copper, and 1 sal ammoniac, in 64 of water, and add 1 part commercial hydrochloric acid. Paint the zinc with this, and leave to dry for 24 hours. Any oil colour will then firmly adhere to it.

To Paint in Imitation of Ground Glass.

White lead, 4 parts; boiled oil, 3 parts; spirits of turpentine, 1 part; add a small quantity of dryers. The colour must be exceedingly thin, and put on the panes of glass with a large brush in as even a manner as possible. Dab the paint over lightly with a pad of cotton-wool covered with an old linen rag.

Hydraulic Cement Paint.

Hydraulic cement mixed with oil forms an incombustible and waterproof paint for roofs of buildings, outhouses, etc.

Outside Whitewash.

Slaked lime, ½ bushel. Add common salt, 1 lb.; sulphate of zinc, ½ lb.; sweet milk, 1 gallon.

Flexible Paint.

Used for painting on canvas. 2½ lbs. good yellow soap dissolved in 1½ gallon boiling water; grind the hot solution with 3½ gallons of good oil paint.

Red Paint, quick drying (8 to 20 Minutes).

(Used for Pillar-boxes.)

Japanner's gold size	40 per cent.
Red lead	60 „

When dry, varnish with outside oak varnish.

Waterproof Paints.*

For General Purposes.

(1.)

2 gallons linseed oil, boiled with 11 ozs. each of rosin and litharge, 1½ oz. each of minium and umber; add gradually 8 ozs. of sulphate of zinc and a solution of 12 ozs. of potassium hydrate, and a like quantity of alum in 4 gallons of water. For preparing the ground colour, compound 10 lbs. of chalk and 2 lbs. of zinc white with ¾ gallon of water in which 1½ oz. of alum has been previously dissolved, and mix with this a solution of 1½ lb. of glue in ½ gallon of water. This ground paint is mixed with 4 to 5 lbs. of the above composition, and the mixture diluted with petroleum.

(2.)

12 ozs. of melted rosin, thoroughly mixed with 6 gallons of fish oil and 1 lb. of melted sulphur, and some ochre or any other colouring substance rubbed up with linseed oil. Apply several coats of the hot composition with a brush. The first coat should be very thin. Suitable for either wood or stone.

For Casks and Waterspouts.

Boiled oil, 1 part; charcoal, finely powdered, 1 part. Mix to consistence of paint.

For Vessels and Submarine Works.

Sulphate of copper, 400 lbs.; grape sugar, 100 lbs.; concentrated solution of potash, 200 lbs. The precipitate of hydrated oxide of copper formed by heating this mixture is filtered, dried, and mixed with 8 lbs. of 75 per cent. carbolic acid. Heat the mass moderately, and add about 12 gallons of crude linseed oil. When the paint is to be used it is reduced with linseed oil, and then applied. This composition is claimed to prevent the deposition of marine animals on the surface to which it is applied.

Paints for Waterproofing Outside Walls.

(1.)

Rosin, 4½ ozs.; litharge, 3 ozs., boiled in 1 pint of clear linseed oil until the wooden spatula used for stirring becomes brown. Give the walls 2 or 3 coats of this, preferably on a hot and dry summer's day.

(2.)

A solution of paraffin wax in heavy coal-tar oil is excellent for painting houses, and especially walls exposed to the action of the weather. Several experiments in painting damp walls with this solution have given very satisfactory results. Wall-paper which formerly became moist and detached from the walls during rainy weather remained perfectly dry after the wall had been painted with this solution, which is prepared by dissolving 1 part of paraffin wax in 2 to 3 parts of coal-tar oil at a moderate heat. A sufficient quantity of oil must be used so that the solution does not entirely congeal on cooling. To heat the paint while applying it, place the vessel containing it in hot water. It is best to apply the solution on a warm day, when the bricks are dry. Generally 1 coat is sufficient, but even if 2 coats are given the cost is considerably less than that of oil paint.

Paint for Wooden Floors.

Soak 2 ozs. good light-coloured glue in cold water for 12 hours, and dissolve it with constant stirring in thick milk of lime (prepared from 1 lb. of caustic lime) heated to the boiling-point. Stir in 8¾ ozs. linseed oil. Mix with any colour not affected by lime, and dilute with water if necessary. For yellow-brown or brown-red colours, boil in the ground colour ⅓th of its volume of a solution of shellac and borax. A coat of varnish produces a bright surface.

Paint for Red Brick Floors.

Wash the bricks with soap-water containing $\frac{1}{20}$th part of carbonate of soda. Dissolve 1 part of glue in 16 of boiling water and 4 parts of red ochre, and stir the mass thoroughly together. Apply 2 coats of this to the bricks, and then give a coat of linseed oil varnish.

---

* It has been proved that no paint film, of which linseed oil is one of the chief constituents, can be made *thoroughly* impervious to moisture.

Preservative Solution for Stonework.

1 part white shellac, dissolved in 8 parts wood spirit. Apply to surface by means of a watering pot provided with a rose.

Paint for Roofs.

Pulverised slate (argillaceous schist), 35 parts; pulverised mica slate (mica schist), 30 parts; pulverised rosin, 35 parts; mix with ½ its volume of pure coal-tar, and boil to a fluid mass. This paint gives a very durable and pliant coating, which does not melt in the greatest heat of summer nor crack or break in the greatest cold. It resists moisture, and retains its lustre and smooth surface. It will last for 4 or 5 years.

Paints for Preserving Wooden Posts.

(1.)

50 parts rosin, 40 parts powdered chalk, 4 parts linseed oil; melt together in an iron boiler, add 1 part of natural cupric oxide, and stir very carefully into the mixture 1 part of sulphuric acid. Apply with a stiff brush. When dry the mass forms a coating as hard as stone.

(2.)

1½ part rosin (melted), 48 parts fish oil, 1½ part sulphur. When the mixture is thoroughly combined and liquid, add sufficient ochre rubbed up with linseed oil to give the desired shade of colour. Apply the mass while still warm in as thin a coat as possible, and in a few days, when the first coat is dry, repeat the operation.

Paint for Felt Roofing.

Washed graphite, 2 parts; red ochre, 2 parts; cement, 16 parts; barium sulphate, 16 parts; plumbic oxide, 6 parts. These materials to be ground in an oil varnish prepared as follows: 100 parts of good linseed oil are boiled for 8 hours in a copper boiler with 5 per cent. of pyrolusite, 10 parts of flowers of sulphur and 20 parts of French pitch are then dissolved in the mixture, and the mass filtered before it becomes cold. 25 lbs. of this composition and 1½ gallons of linseed oil varnish or linseed oil, for reducing the paint, are sufficient to give 2 coats to 1,000 square feet of roof surface. The first coat, while still wet, is uniformly covered with fine dry sand by means of a sieve. The sanding should be done during the progress of the painting, so that the workman is not obliged to step on to the wet paint. The free sand is renewed with a broom before the second coat is given, and it is best to apply this 8 days after the first. The second coat need not be sanded, its purpose being to combine with the first to form an insoluble mass hard as stone, and to give to the roof a neat, finished appearance.

Quickly-drying Oil Paint.

Boil for 15 minutes in an earthenware pot 1 part of soft curd soap in 3 parts of water. Pour the mass through a colander, wash it with cold water, and press out the water in a linen cloth. To 1 part of the curd soap add ¼ part of unslaked lime and ¾ part of water. Triturate the fat slime thus formed in oil or water with the necessary pigments. Walls, ceilings, stairs—in short, anything of stone, plaster of Paris, or zinc—can be painted with this. If the paint is to be used on wood, add $\frac{1}{10}$ part of linseed oil. Ochre, chrome yellow, Berlin blue, indigo, lead, and zinc, are best adapted for colouring substances. The mixture dries so quickly that 3 coats can be applied in a day. It is entirely without odour, and is about one-third the cost of ordinary oil paint.

Heat-Proof Paint.

Paint with good heat-proof properties, for smoke boxes, etc., can be made from 3 lbs. lamp black, 2 lbs. black lead, 1 lb. of black manganese oxide; these are mixed together; add ½ gal. of gold size, 1 pint of turpentine, and ½ pint of terebene; this, when thoroughly mixed in, will bring the mixture to the consistency of paint, and if about two coats of this are applied to surfaces exposed to heat, they will be found to resist same very well.

Fire-resisting Paint.

(1.)

20 lbs. finely pulverised glass, 20 lbs. finely pulverised porcelain, 20 lbs. any sort of stone in powder, 10 lbs. calcined lime, and 30 lbs. water glass (silicate of soda). The solid elements, having been powdered as finely as possible and sifted, are moistened and then intimately mixed with the water glass. This yields a syrupy mass that may be employed for painting, either alone or mixed with colour. The coating is applied with a brush, as other paints are, as uniformly as possible over the surface to be protected. The first coat hardens immediately, and a second one may be applied 6 hours or more afterwards; two coats are sufficient. The paint must be used immediately after it is made up.

(2.)

The most practical means so far discovered by the United States Forest Products Laboratory, Madison, Wis., for economically rendering small quantities of wood fire-resistant consists in the

use of fire-retardant paints. Ordinary whitewash or calcimine has proved in tests to be as fire-resistant as any paint covering tried, and it also possesses the advantages of cheapness and ease of application. While it will not prevent the burning of wood continuously exposed to a high temperature, a good coat of calcimine will decrease the likelihood of a blaze spreading from small sources of fire, such as flying sparks and matches. Calcimine is naturally more effective for interior than for exterior use. For work of the latter class the Forest Products Laboratory has developed an effective paint composed of linseed oil, zinc borate, and chrome green, which has maintained its fire-resisting properties through more than three years of exposure to the weather.

Heat-indicating Paint.

A paint for indicating an excessive rise of temperature in machinery bearings is composed essentially of a mixture of the double iodide of silver and mercury and copper mercuric iodide. The former is a pale yellow powder at normal temperatures, but turns to a vivid carmine at 90° to 100° C., while the copper salt, which is normally of a strong scarlet vermillion, changes to a chocolate brown at 60° to 70° C. A mixture of the two in the proportion of 85 per cent. of the copper salt and 15 per cent. of the silver changes promptly from vermillion to nearly black at 60° to 70° C. The paint is made with the aid of white shellac spirit varnish (100 grms. of the mixture to 70 cub. cm. of the spirit), and is applied in the form of a band or bull's-eye to the bearing. After the paint has become dry it is to receive a coat of colourless oil-proof varnish.

See also p. 962.

Painting Portland Cement.

Portland cement work which is to be painted must be thoroughly hardened and dry. It is advisable to let the work stand for a year before oil paints are applied. The durability of the paint will be assured by, first, brushing over the surface with dilute sulphuric acid—one part of acid to 100 parts water—and allowed to dry before painting. A preparatory coating for oil paint is a solution of common water glass in three or four parts of water. Two applications of this, followed by a washing with water, and then another application of water glass, will be found effective.

Coal-Tar Paint.

(1) Coal-tar, 8 parts; Portland cement, 1 part; kerosene oil, 1 part. (2) Coal-tar 16, Portland cement 4, and kerosene 3 parts. The Portland cement neutralises the action of the tar on iron and steel, while the kerosene acts as dryer. It is suitable for painting ironwork of all kinds, and is a satisfactory coating, it is said, for ships' sides, and may also be used on galvanised iron.

Graphite Paint.

The best and longest records of satisfactory protection against corrosion are said to be held by graphitepaints containing silica in intimate admixture with tough crystalline foliated graphite.

An example of this is the 'Foliac' Silica-Graphite Paint manufactured by *Graphite Products, Ltd., Battersea*, which is British manufactured throughout, and has been specified for a large number of steel structures, including Admiralty airship sheds, oil fuel tanks, gas holders, docks, bridges, station roofs, railway wagons, &c.

The relative covering power of foliated silica graphite paint is very high, and owing to the lubricating properties of the pigment the speed of application to the surface is very much more rapid than with other linseed oil paints. Owing to the large adhesion surface between the vehicle and the foliated graphite a very flexible tough paint is obtained which stands wearing action due to dust, for example, much better than paints which become brittle on drying. The resistance of the pigment to the action of the atmosphere found in industrial districts is due, of course, to the fact that it is chemically inert.

Bituminous Paints.

Bituminous paint is a good preventive to rust as it adheres closely to the material to be protected, it is strongly resistant to sulphurous vapours prevalent in the air of industrial centres, and very few of the mineral acids attack it, with the exception of nitric acid. Nitrous fumes have little or no action on the better bituminous paints. A good bituminous paint should dry within four or five hours, and the chances of injury by rain or similar eventualities during the setting are, therefore, correspondingly small. A high-class bituminous paint may be applied at a cost of something like a farthing per square foot with two coats of the paint applied. The life of a well-compounded bituminous paint extends up to twenty years' efficient protection.

Luminous Paint.

Mix 50 parts of lime with 20 parts of flowers of sulphur, heat them together in a closed crucible until all fumes cease to be evolved. When quite cold grind the product up with varnish or paint which is quite free from lead. Luminous paint produced from oyster shells is the most efficient in retaining its luminosity after dark. Take clean shells and, after washing them in warm water, place them in the fire for half an hour, and when cool, after removal, pound them up very small and fine, taking away any grey portions as being of no use, then put this powder in a crucible with alternate layers of flowers of sulphur, place on the lid and cement it round with sand made into a stiff paste with beer; as soon as this is dry, place the crucible in the fire and bake for one hour. Wait until quite cold before opening the lid. The product should be white; any grey portions must be separated as non-luminous. Sift it through fine muslin, and mix with either varnish or gum water. For use with buoys or in places exposed to the weather, varnish of the best quality only must be used.

VARNISHES.

(Incombustible Varnish for Wood.

An application of a solution of equal parts of alum and isinglass to the place exposed to the flame prevents ignition, but not the transmission of heat. By coating wooden vessels with this varnish fluids may be boiled in them over an ordinary fire.

Varnish for Wood not acted upon by Boiling Water.

Boil in an untinned copper boiler 750 parts of linseed oil. Suspend in this, in a bag which must not touch the bottom, 150 parts of litharge and 90 parts of pulverised minium. Let the oil boil until it has assumed a dark brown colour; then remove the bag, and replace it by one containing 7 to 8 bulbs of garlic. Now melt 500 parts of pulverised amber in 60 parts of linseed oil over a strong fire; add it while boiling to the prepared linseed oil, and let it boil for 2 to 3 minutes longer, stirring it vigorously. Then take it from the fire, allow it to settle, pour off the clear liquid, and when cold put it in bottles, which should be hermetically closed.

Quick-drying Varnish.

A quick-drying varnish that is less liable to crack than that made from kauri gum is made in the United States from the nuts of the Chinese wood oil tree (*Aleurites fordii*). The tung (or wood) oil has also been found of special value for waterproofing cement.

Varnish to prevent India-rubber Gas-tubing from Leaking.

Treacle, 1½ part; gum arabic, 2 parts; white wine, 7 parts; strong alcohol, 3½ parts.

Waterproofing Material.

A new French material for waterproofing leather, cloth, paper, and other materials, consists of a mixture of eight parts of amyl acetate and four of castor oil, with one part of sulphur chloride stirred into it. This forms a jelly, giving off hydrochloric acid; it liquefies after being kept tightly covered a few days, and, the acid being then neutralised with barium carbonate, gives a colourless solution on filtering. To make a varnish, nitrocellulose is dissolved in the liquid after the addition of alcohol or benzine

Cellulose Lacquers and Varnishes.

Cellulose lacquers and varnishes are extensively used for motor-cars and other purposes where a brilliant finish coupled with great resistance to weather is desired. They are made by dissolving nitrocellulose or cellulose acetate in amyl nitrate or acetate, castor-oil, or other suitable solvent, and may be applied with a spray or a brush, according to the nature of the lacquer and the surface to be decorated.

Cellulose lacquers have been used for twenty-five years or more, but their great popularity is of recent growth. In many instances they have replaced oil enamels, but in numerous other cases the reverse has occurred. For motor-cars, the American cellulose lacquer finish is superior to the American oil-varnish finish, but inferior to the English oil-varnish. English cellulose lacquer finish is superior to the American product and approaches, but is not quite equal to, English oil-varnish. In appearance the cellulose lacquer finish and the oil-varnish finish are almost equal, and it is a question of workmanship rather than material which gives the advantage, sometimes to one and sometimes to the other. The relative durability remains to be proved, short time tests being unreliable. Cellulose lacquer is more liable to crack under vibration, but is more resistant to changes in temperature, and whilst it is harder than oil-varnish it is more brittle and more liable to peel.

The cost of cellulose lacquer is greater than that of oil-varnish, but in large quantities it is cheaper to apply, so that the cost of covering a given area is less with cellulose than with oil-varnish. Although the use of cellulose lacquers is increasing rapidly, these materials have not superseded oil-paints, water-paints, and stove-enamels. They are limited in scope, cannot be repaired so readily when damaged, and many of them are inflammable and produce vapours injurious to the health of those applying them. These are temporary disadvantages which will probably disappear as still further improvements are made in cellulose lacquers. In selecting such lacquers care should be taken to avoid those of poor quality, of which there are too many available.

METAL LACQUERS AND BRONZES.

Lacquer for Iron and Steel.

Mastic, 10 parts; camphor, 5 parts; sandarach, 15 parts; elemi, 5 parts. Dissolve in alcohol and apply without heat.

A Rustless Coating for Steel.

A solution of white wax in benzine applied with a camel-hair brush. When the film of wax hardens, the bulk of it is wiped off with a chamois leather, just sufficient remaining to prevent rust, but not to be noticeable.

Angus Smith's Coating for Pipes.

Coal Tar 1 cwt., Tallow 7 lbs., Quick Lime (slaked) 10 lbs., Pine Resin 4 lbs., Coal Naphtha, sufficient to thin the composition to a degree suitable for proper coating. Heat mixture, and immerse pipes, and allow to remain until the same temperature is diffused through the mass; then withdraw pipes. This treatment leaves a very firm and hard coating of pitch. It is very essential that the mixture be heated to a proper degree, viz., 350° to 450° F. If heated too much the pitch will not adhere properly, but will scale off.

Bronzing Liquids.

(1.)

Sulphate of copper, 1 oz.; sweet spirits of nitre, 1 oz.; water, 1 pint.

(2.)

Solution of chloride of platinum, laid on surface with a feather. When dry, blacklead over with an ordinary blacklead brush, and then lacquer.

(3.)

Boil 1 oz. of ammonium carbonate and a like quantity of blue vitriol in 1½ pint of vinegar until the latter is nearly evaporated. Then add 1½ pint of vinegar in which has been dissolved ½ drachm of oxalic acid and a like quantity of sal ammoniac. Place the mixture (known as Walker's Chemical Bronze) over the fire until it commences to boil, then allow it to cool; filter, and put by in well-closed bottles.

If a medal, etc., is to be bronzed, it is first thoroughly cleansed, then heated, and the liquid applied by means of a badger-hair brush. In a short time boiling water is poured over the medal, and when dry it is rubbed with a cotton rag dipped in oil, and then with dry cotton.

Browning for Gun Barrels.

Tincture of muriate of iron, 1 oz.; nitric ether, 1 oz.; sulphate of copper, 4 scruples; rain-water, 1 pint. When the barrel is finished let it remain in lime-water for a short time; then scratchbrush and apply bronzing.

Lacquer for Gun Barrels after Browning.

Shellac, 1 oz.; dragon's blood, ½ oz.; rectified spirit, 1 quart. Dissolve and filter.

To Chemically Blacken Brass.

Dissolve copper in nitric acid (out of doors) until all action ceases; when cold decant into another jar.

Sand-blast work, or clean in hot lye and soda; dry in sawdust; heat to 212° F.; immerse in the (cold) nitrate solution; remove and heat again sufficiently to dry off solution and burn off green colour; repeat if necessary; cool and free from oxide by brushing; dip in ammonia; rub dry with soft cloth or in sawdust—work is then brown. To make it dead black, heat just enough not to burn hands, and rub with soft leather and fine olive oil; heat, to dry oil.

Highly-polished work, if well cleaned and dipped in commercial ammonia before applying nitrate, will take a permanent black.

Sand-blasted work takes a black that cannot be removed by ordinary wear.

Black-bronzing Aluminium.

(1) Immerse the articles, after being thoroughly cleaned, in a hot solution containing 8 oz. of white arsenic, 8 oz. of iron sulphate, ¾ gallon of hydrochloric acid, and ¾ gallon of water. When sufficiently blackened the articles are removed, washed and lacquered. A more adhesive deposit may be obtained by adding to the solution a small quantity of ammonium molybdate and yellow prussiate of potash. (2) Paint the articles with a solution made by dissolving 60 grammes of copper chloride in 300 c.c. of water and add ammonia in excess to re-dissolve the precipitate first formed. Then heat the articles, care being taken not to melt the aluminium. A deeper black may be got by repeating the process, or by dipping the articles in a solution of sodium sulphide.

Black Finish on Steel Shears, etc.

Prepare a saturated solution of caustic soda and add about ¼ lb. of saltpetre to a five-gallon solution. Boil the solution for a short time, and allow it to cool. The clear liquid should only be used, and this should be brought to the boiling point in an iron kettle. The articles should be wired as for plating and immersed in the solution. The articles will take on a grey colour at once with black underneath, and should be left in the solution until the grey finish disappears and a beautiful black remains. Rinse the articles in cold water, dry in sawdust, oil with linseed oil, and wipe clean. The resulting finish will be a fine blue-black that wears well.

LUBRICANTS AND OILS.*

Greases for Railway Axles.

(1.)

Water, 1 gallon; palm oil, 6 lbs.; clean tallow, 3 lbs.; common soda, ½ lb.

(2.)

Tallow, 8 lbs.; palm oil, 10 lbs. Heat to 212° F., and well stir.

Antifriction Grease.

(1.)

Tallow, 100 lbs.; palm oil, 70 lbs. Boil together, and when cooled to 80° F. strain through a sieve and mix with 28 lbs. common soda and 1½ gallon of water.

(2.)

Blacklead, 1 part; lard, 4 parts.

Rosin-Oil Soap.

90 lbs. powdered slaked lime, stirred into 100 lbs. rosin oil. Heat the mixture, constantly stirring it well until a uniform paste of the consistence of syrup is obtained. This rosin oil is a component of all the patent wagon greases.

Blue Patent Grease.

2 lbs. powdered slaked lime, heated in 550 lbs. of crude rosin oil for 1 hour, and then allowed to cool. Skim the oil, and stir in 10 to 12 lbs. of rosin-oil soap, until the compound is of a butter consistency and of a blue colour.

Yellow Patent Grease.

1 part turpentine, 20 parts caustic lye. Add to 350 parts of blue grease.

Black Patent Grease.

2 parts lampblack, 110 parts blue grease.

Patent Palm-Oil Wagon Grease.

Melt 10 lbs. rosin-oil soap in 10 lbs. palm oil: add 550 lbs. rosin oil, with as much rosin-oil soap as will give the whole the consistence of butter; finally, add 7½ to 10 lbs. of caustic soda lye.

Adhesive Grease for Machine Belts.

Lubricate the belts with fish oil to which 10 per cent. of tallow has been added. This will make them flexible, and augment their friction on the pulleys.

Grease for Waterproofing Leather.

Oleic acid, 24 parts; crude stearic acid, 6 parts; ammoniacal soap, 18 parts; extract of tannin, 6 parts; water, 24 parts. Melt the oleic acid together with the stearic acid; then add gradually the ammoniacal soap, the extract of tannin, and finally the water. The ammoniacal soap is obtained by adding to heated oleic acid caustic ammonia until, after continued stirring, the odour of ammonia remains apparent and the whole congeals to a jelly-like mass.

Cooling Compound for Hot Bearings.

(1.)

Mercurial ointment mixed with black cylinder oil and applied every quarter of an hour, or as often as expedient. The following is also recommended as a good cooling compound for heavy bearings:—Tallow, 2 lbs.; plumbago, 6 ozs.; sugar of lead, 4 ozs. Melt the tallow with gentle heat, and add the other ingredients, stirring until cold. For lubricating gearing, wooden cogs, etc., nothing better need be used than a thin mixture of soft soap and black lead.

(2.)

For cooling a hot bearing Professor Lecocq, of the Charleroi Higher Industrial School, recommends that the oil usually employed for lubrication be dissolved in an equal quantity of petroleum spirit, the evaporation of which latter will, he says, afford the cooling desired.

---

* See also pages 977-992.

Watchmaker's Oil.

Expose the best olive oil to a temperature a few degrees below the freezing point, which will cause all foreign substances to separate. Pour off carefully the supernatant clear oil, and filter through a cup of linden wood or pith of elder wood. By this process an oil is obtained which will remain liquid for several years, and does not attack the delicate machinery.

Neat's-foot oil treated in the above manner furnishes a less useful oil, since it loses much fatty matter by exposure to cold.

A very useful oil is obtained by dissolving 1 part of pure neat's-foot oil in 3 of pure benzine. Allow the compound to remain for several days in a closed vessel; then filter, and expose the solution to a temperature of 40° F., at which it is again filtered, and the benzine distilled off. The oil should be kept in small, dark vials protected from the air.

A very fine lubricant for clocks and watches is, according to Artemus, obtained by mixing 2 parts of solar oil with 1 of rape-seed oil.

To test the fitness of Oils for Lubricating Watches and Clocks.

Pour a drop of the oil to be tested upon different metal plates, as iron, brass, tin, lead, etc.; keep them in a place free from dust, and examine the drops during 8 to 14 days in regard to their liquidity. Oil remaining liquid after the lapse of this time can be safely used.

Viscosity of Various Standard Oils.

Description.	Viscosity.	
	At 70° F.	At 120° F.
Sperm oil	100	45
Whale oil	190	70
Olive oil	213	75
Lard oil	225	78
Neatsfoot oil	247	80
Rape-seed oil	250	88
Axle oil	600	120
Valve oil	—	550
Cylinder oil	—	700

In the above table sperm oil is taken as the standard for viscosity at 70° F.

The viscosity of thick oils can be greatly reduced by adding 8 per cent. of naphthalene to the oil.

An objectionable characteristic in an oil is its tendency to become resinous with use, due to the oil undergoing the process of oxidation. This change in the oil indicates, to some extent, the degree of refining process the oil has undergone. A simple test can be made in the following way:—Place a small quantity of oil in a glass beaker and put in a nearly equal amount of nitric acid. Should the oil have no tendency to gum, the acid and oil will combine and get very thick, while should there be any objectionable characteristic the oil will remain thin.

CLEANING AND PRESERVATIVE COMPOSITIONS.

To clean Brass.

Oxalic acid, 1 oz. Rotten stone, 6 oz.; powdered gum arabic, ½ oz.; sweet oil, 1 oz. Rub on with piece of rag.

Soap for cleaning Metal-work.

The soaps used for cleaning metal-work usually consist of mixtures of vaseline, oleic acid, and fat, mixed with a small quantity of rouge. When freshly prepared they leave nothing to be desired; but, unfortunately, such mixtures soon turn rancid and become unfit for use. A newer soap for metal-work, which is stated to be free from this objection, is made from cocoanut butter in the following way:—2·5 kilogrammes of the butter are melted in an iron vessel, together with a little water, and to the mixture is added, with constant stirring, 180 grammes of chalk, 87·5 grammes of alum, 87·5 grammes of cream of tartar, and 87·5 grammes of white lead. This mixture is then poured into moulds and allowed to solidify. The soap so obtained is made into a paste with water, rubbed over the metal to be cleaned, and finally removed by a dry rag or chamois leather.

To clean Grease from Paper.

(1.)

Warm the spotted part, and press blotting-paper upon it until all the grease is extracted that is practicable by this method; then with a brush apply very hot turpentine, and wash off with alcohol.

(2.)

Apply benzine collas freely to the spot.

To clean Marble.

Powdered chalk, 1 part; powdered pumice stone, 1 part; soda, 2 parts. Mix with water. Paint over marble; then clean, and wash off with soap and water.

To clean Grease from Stone or Marble.

Soft soap, 1 part; fuller's earth, 2 parts; potash, 1 part. Mix with boiling water. Lay it on the spots, and let it remain for a few hours.

A Solvent for Rust.

It is often very difficult, and sometimes impossible, to remove rust from articles made of iron. Those which are very thickly coated are most easily cleaned by being immersed in a solution (nearly saturated) of chloride of tin. The length of time they remain in this bath is determined by the thickness of the coating of rust. Generally twelve to twenty-four hours is long enough.

To cleanse Paint Brushes from Dried-in Paint.

Suspend the brush in a tumbler containing a solution of 1 part of crystallised sodium carbonate in 3 of water, in such a manner that it hangs several inches from the bottom of the tumbler. Let it stand from 12 to 24 hours in a moderately warm place (140° to 150° F.). The dried paint will be softened so much that it can be easily washed out with soap and water. Brushes which have become as hard as stone can be restored by this process.

To remove Rust from Iron.

(1.)

Freely apply turpentine or paraffin oil, leave for twelve hours, and then rub with the finest emery cloth.

(2.)

Dip in strong hot potash bath, for about ½ hour. Then immerse in a cold muriatic acid pickling solution—2 parts water, 1 acid. This removes rust in a few minutes, the metal being attacked but very little. Without the potash it will take about 65 minutes against 4 when both baths are used. The appearance of the rust when treated is black and soft and it can almost be entirely rubbed off with the hands. The metal so treated has a smooth, glossy finish.

(3.)

A dip of 40 parts of muriatic acid and 60 parts of water is effective for removing rust. After the rust has been removed, it is necessary to dip the steel in a strong alkaline bath to remove every trace of acid. The alkaline solution usually employed for this purpose is composed of 2 oz. each of soda ash, sodium cyanide, and caustic lime.

To Remove Rust from Iron Electrically.

A very simple and effective way of cleaning rusted iron articles, no matter how badly they are rusted, consists in attaching a piece of ordinary zinc to the articles, and then letting them lie in water to which a little sulphuric acid is added. They should be left immersed for several days, or a week, until the rust has entirely disappeared, the time depending on how deeply they were rusted. If there is much rust, a little sulphuric acid should be added occasionally. The essential part of the process is that the zinc must be in good electrical contact with the iron; a good way is to twist an iron wire tightly around the object, and connect this with the zinc, for which a remnant of a battery zinc is suitable, as it has a binding post. Besides the simplicity of this process, it has the great advantage that the iron itself is not attacked in the least as long as the zinc is in good electrical contact with it. When there is only a little rust, a galvanised iron wire wrapped around the object will take the place of the zinc, provided the acid is not too strong. The articles will come out a dark grey or black colour, and should then be washed thoroughly and oiled. The method is specially applicable to objects with sharp corners or edges, or to files and other articles on which buffing wheels ought not to be used. The rusted iron and the zinc make a short-circuited battery, the action of which reduces the rust back to iron, this action continuing as long as any rust is left.

To keep Machinery from Rusting.

Take 1 oz. of camphor, dissolve it in 1 lb. of melted lard; mix with it (after removing the scum) as much fine blacklead as will give it an iron colour. Clean the machinery, and smear it with this mixture. After 24 hours rub clean with soft linen cloth. It is stated that this mixture will keep machinery clean for months under ordinary circumstances.

To protect Iron and Steel from Rust.

The following method is but little known, although it deserves preference over many others: Add $1\frac{3}{4}$ pints of cold water to 7 ozs. of quicklime. Let the mixture stand until the supernatant fluid is entirely clear. Then pour this off, and mix it with enough olive oil to form a thick cream, or rather to the consistency of melted and recongealed butter. Grease the articles of iron or steel with this compound, and then wrap them up in paper; or, if this cannot be done, apply the mixture somewhat more thickly.

To keep Tools from Rusting.

Half-ounce camphor dissolved in 1 lb. melted lard; skim and mix in as much black-lead as will give it an iron colour. Smear tools, and after 24 hours rub clean with soft linen cloth.

Or, 6 oz. lard to 1 oz. rosin. When semi-fluid it is ready for use.

Or, use vaseline, to which, when warm, a little powdered camphor has been added.

To remove Rust from Tools.

Tools which have become very rusty should be treated with a chemical solution, instead of trying to scour the rust off by means of emery cloth. A good solution for removing rust may be made as follows. Into one quart of distilled water dissolve, little by little, sufficient chloride of tin to obtain a saturated solution, that is, until the water will not dissolve any more of the salt. Put the tool into a receptacle containing the solution and let it stand over night. In the morning rinse the solution off in running water and dry thoroughly with a piece of chamois or cloth.

Blueing Steel.

Outfit.

The outfit consists of a cast-iron kettle, one tank for boiling water, and one tank for oil (aquiline). The mixture consists of nine parts of saltpetre, by weight, and one part pyrolusite. The articles are hung in perforated baskets. A scraper is necessary for the melting kettle to stir the solution and to scrape the sediment from the bottom.

Method.

The desired temperature for treatment is obtained when all the mixture has melted and begun to boil, and when a pinch of fine sawdust thrown in bursts into flame the moment it reaches the surface. The temperature must be kept constant to give good results. In operation, the full basket may be hung on the chain at one end of a lever and lowered into the solution. The articles are left in for three minutes, then are slowly lifted out to allow the surplus solution to drain off: they are then dipped into hot water to clean off the solution; after the water has drained off, the articles are dipped into the oil and taken out as quickly as possible and allowed to drain. It is essential to note that there be no rust on the work, and that red-hot cast iron is attacked by these chemicals.

Blueing Small Screws.

Use a boiling bath composed of:

Water	1 gallon.
Hyposulphite of soda	2 ozs.
Acetate of lead	2 „

The hyposulphite of soda and the acetate of lead are first dissolved in the water and the whole is then brought up to boiling point. The work, which must be absolutely clean and free of grease, and preferably polished, is immersed in the bath for a few seconds, and then withdrawn. At first the work will be a kind of yellow, changing to red and then to blue almost immediately. The work is rinsed in water and quickly dried. Changing the length of time during which the work is immersed in the bath will give varying depths of colour. When the desired tint is obtained, note the time immersed, and give subsequent dippings the same period in the bath.

The brilliancy of the blues obtained by the above method is greatly enhanced if the work is copper plated before immersion in the colouring bath. The plating may be accomplished by the dipping process. To a quantity of distilled water add all the copper sulphate it will dissolve, then for every four ounces of distilled water add from 10 to 14 drops of sulphuric acid. Start with 10 drops in the first instance and add more sulphuric acid if required. Before coppering it is absolutely essential that the work be free from grease. It should be noted that in all colouring processes the higher the initial polish on the work the greater the brilliance of the finished work.
(*'Machinery.'*)

Blueing Small Hardened Steel Springs Without Heating.

Thoroughly clean the springs in boiling lime water and afterwards remove any remaining lime by means of a brush. Dip the springs in a nitric acid bath; wipe clean and oil; linseed oil is generally used for this purpose. (*W. R., 'Machinery.'*)

Waterproof and Fire-Resisting Boards.

The boards are first laid in a waterglass solution of 5° to 10° Bé., where they are left 10 to 12 hours, when they are taken out and allowed to drip off. After drying, they are placed in a solution (gravity 2° to 3° Bé.) of calcium chloride, magnesium chloride, and ammonium chloride. In this they are left four to six hours, and after dripping off and drying again, they are ready for use.

MISCELLANEOUS.

To Prevent Rusting-in of Screws.

In machines exposed to heat or moist air the screws soon rust in, even with the use of oil, which later on renders it difficult to take the machines apart. By dipping the screws before use in a thin paste of graphite and oil they can be readily taken out, even after years.

Drilling Glass.

To drill holes in glass a common steel drill, well made and well tempered, is the best tool. Whilst drilling, the hole should be moistened with turpentine in which some camphor has been dissolved.

To drill a large hole in thin glass, make in a piece of wood a hole of the size required, and fasten the wood with beeswax upon the glass so as to act as a guide. A piece of brass or copper tubing, of the size of the hole required, is placed in the hole in the wood, supplied with emery powder and water, and is twirled round between the fingers or by means of a bow-string. This will cut a hole in a few minutes.

To Divide Glass Bottles.

Breaking glass tubes or vessels with a clean edge by the aid of a string dipped in an inflammable oil is a well-known method, but the latter is not suitable for large vessels, such as a carboy; to break such vessels, fill to point required with cold water, then pour boiling oil over surface of water: before oil has time to cool, dash cold water on outside of vessel, when a clean break is said to result.

A still better method is to make a small mark, with a triangular file, at the point where the break or division is required. A tiny gas flame, not larger than $\frac{1}{8}$ in. diameter, is then applied to the file-mark. If a crack does not start quickly the hot glass is wetted with a drop of water. When a crack has started the flame is held in contact with the glass, just in front of the crack; the crack will then extend to the flame and by causing the flame to travel, step by step around the vessel, complete severence will be effected with accuracy and certainty.

To Cut Glass Tubing of Large Diameter.

Nick the glass tube with a file or a cutter at the point where the fracture is desired. Wrap three or four thicknesses of blotting paper around the tube about $\frac{1}{2}$ in. from each side of the mark, the blotting paper being held in place by copper wires. Soak the blotters with water, and expose the narrow section of tube between the two wet blotters to the heat of a bunsen burner. The flame will cause a fracture starting at the file nick and extending in almost a straight line around the tube. The method describes for glass bottles (above) may also be used.

Cutting Glass under Water.

Cutting a glass sheet with a pair of scissors may seem difficult, but it is not, although the job must be done under water and both the glass and scissors must be submerged. A good way is to first cut a paper the size or shape of the glass desired; place it on the under side of the glass for a pattern. It is not expected that it is possible to cut through the centre of a large piece of glass, but by trimming a little at a time a good job can be done. The cutting sensation is a good deal the same as that of cutting cardboard.

To make Ivory and Bone Permanently White.

Hydrated oxide of zinc is dissolved in ammonia and the articles laid in it. To remove the yellow tint, a few drops of an aqueous solution of blue vitriol is added; after impregnation the articles are repeatedly washed with cold water, dried in the air and polished. The zinc-oxide of ammonia solution is prepared as follows:—40 parts by weight water mixed with 25 parts of pure zinc, with (after a quarter of an hour) 50 parts concentrated hydrochloric acid added. To the zinc solution 150 parts hot water is added, then (gradually stirring the while) caustic ammonia until the precipitated white hydrated oxide of zinc is dissolved.

Hard Rubber.

The finest grade of hard rubber, such as is found in a good comb or fountain pen, may contain 75 per cent. rubber and 25 per cent. sulphur, and may have been vulcanised ten hours. The specific gravity of pure hard rubber ranges from 1·12 to 1·25. The tensile strength in the finest and purest grades may be over three tons, and the dielectric strength is specified by the United States Navy for sheets at 10,000 volts per $\frac{1}{32}$ in. of thickness.

Fibre.

There are three kinds of fibre in general use—viz., two kinds of vulcanised fibre, known as hard and flexible, and horn fibre.

The flexible is restricted to such uses as pump valves, washers and gaskets. The tensile strength of vulcanised fibre varies from 10,000 lbs. to 20,000 lbs. per sq. in. (as compared with 3,000 lbs. to 6,000 lbs. for leather). Its resistance to compression varies from 40,000 lbs. to 60,000 lbs. per sq. in. (for wood it varies from 3,000 lbs. to 11,000 lbs.). Its resistance to shearing varies from 9,000 lbs. to 13,000 lbs. per sq. in. (compared to wood, with the grain, 225 lbs. to 906 lbs.; to aluminium casting, 12,000 lbs.; and to aluminium forgings, 16,000 lbs.). There is no clearly defined elastic limit, but it approximates 4,000 lbs., and there is no permanent set even at rupture point. The specific gravity is about 1·3, varying from 1·2 to 1·5 (sp. gr. of pure aluminium in a cast state is 2·58; of cork, 0·24; of wood, 0·35 to 1·33). It possesses the strength and density of a metal, yet is elastic and nearly as light as hardwood. A square foot of $\frac{1}{8}$ in. fibre weighs about $\frac{1}{4}$ lb., and the same area of 1 in. stock about 7 lbs.—i.e., about 20 cub. ins. to the pound.

Vulcanised fibre is insoluble in all the ordinary solvents, and is not affected by immersion in alcohol, ammonia, benzine, or any of the animal, vegetable, or mineral oils. It absorbs water freely, and swells when wet, but is not otherwise injured. When heated this fibre does not melt or soften, but at a high temperature it chars and loses its elasticity. Vulcanised fibre is not brittle, and will stand a great amount of pounding and rough usage. It can be machined, and will take a fine polish, but cannot be moulded.

One of the purposes to which vulcanised fibre is being applied is the thrust bearings in light, sensitive, drilling machines. Ball bearings cause endless trouble in this position if one of the balls fractures or chips, and it has been found that a fibre disc answers the purpose admirably. The permeability of the fibre to oil renders it self-lubricating, and its life under these conditions is remarkable.

To Face Oilstones.

On a sheet or plate of iron with an accurately even or straight face (it ought to be planed), scatter a little emery or fine sand, add a little water, and rub the face of the stone on the sheet, renewing the emery or sand and water as requisite, finishing with an addition of water without emery or sand.

Etching and Etching Fluids.

The nearest approach to a perfect protective for general purposes is beeswax of the proper consistency, which can be easily applied in any desired thickness. Before applying the wax it is important that the surface be thoroughly clean and absolutely dry, and the difference in temperature between the wax and the article to be etched should be slight. If it is necessary to dip the piece into melted wax, the article should be kept immersed for a few moments until it acquires the same temperature as the molten wax. The design is cut in the wax and through to the metal, after which the etching liquid is applied.

The following fluids have been found to work satisfactorily:

Iron and Steel.—Hydrochloric acid (full strength) should be used. Nitric acid, however, must not be used.

Brass.—Nitric acid.

Copper.—A mixture containing 2 parts of nitric acid and 1 part of sulphuric acid.

Silver.—Nitric acid, 3 parts; water, 1 part.

Gold.—A mixture containing 1 part of nitric acid and 3 parts of hydrochloric acid. This mixture should be prepared just before being applied, and should be used warm, under a hood or fume closet.

Platinum.—The same mixture as that used for gold.

Lead.—Nitric acid.

Aluminium.—A 10 per cent. solution of caustic soda or potash.

Zinc.—A mixture containing equal parts of hydrochloric acid and water, used warm.

Glass.—Hydrofluoric acid. The article may be immersed in the liquid acid for a few minutes or it may be exposed to the fumes for five to fifteen minutes. Extreme caution should be used in handling this acid, using rubber gloves for the hands and a lead or hard rubber container for the acid. Contact with the skin will cause severe burns, and the action seems to be continuous, producing burns far more severe than those caused by the mineral acids.

All the acids may be used full strength, but if the etching is to be of considerable depth most of them may be diluted with water before applying. This will require more time, but will produce a cleaner cut. The exception to this is the mixture of gold and platinum, which must always be used full strength and applied as warm as the melting point of the wax will permit.

Bending Small Metal Tubes.

Put a cork or plug into one end and fill with slightly damp sand well rammed in, then close with another cork; heat the tube until it is just uncomfortably hot to the hand, and then bend round a bit of board sawn to the required curve.

In making coils and spirals of small tubing, the Bureau of Standards at Washington has adopted the plan of filling the tubes with ice. This has the advantage of being very easily got rid of after the completion of the operation, and has proved very effective. To produce the ice filling, the tube, after charging with water, is immersed in a bath of ice and salt.

To Drill Hard Steel.

Use turpentine instead of oil; it will drill readily even when the drill lubricated with oil will not touch the metal.

Turning and Cutting Aluminium.

One of the best lubricants for cutting aluminium in the lathe is paraffin; this prevents tearing, and enables a better finish to be obtained.

To Remove a Stubborn Nut.

Heat the spanner end and place on nut for a moment or two or apply a red hot bar to the nut; this will expand the nut only, whereas using a blow-lamp, etc., heats both nut and bolt. If the above method fails, the nut should be split.

Silvering a Mirror.

(Up to 14 square inches area.)

Well scrub glass with brush, soap, and hot water; rinse repeatedly in cold water; soak in nitric acid for few minutes; rinse in distilled water. Do not touch surface after soap stage.

Solutions.

(*a*)		(*b*)		(*c*)	
Silver nitrate .	50 grs.	Grape sugar .	50 grs.	Caustic potash .	50 grs.
Distilled water .	1 oz.	Distilled water .	1 oz.	Distilled water .	1 oz.

Add strong ammonia drop by drop to (*a*), when a yellowish precipitate will form, and later liquid will clear. No more ammonia must then be added; swirl after each drop. Add (*c*), when black precipitate will form; add ammonia drop by drop until solution clears; add 2½ ozs. distilled water and mix in sugar solution (*b*). *Immediately* put into dish and carefully insert glass with face (downwards) just below the surface. When sugar is added solution becomes cloudy, so it should only be added when quite ready for use. Leave glass undisturbed for 30 minutes. Remove glass and again wash in distilled water. Drain for few minutes and swish off any drops of water. If cloudy, polish with a pad of cotton wool covered with soft chamois leather and jewellers' rouge, by light circular strokes. Lacquer with No. 2 cold colourless lacquer from Messrs. Gedge, 90 St. John's Street, Clerkenwell. Back with Brunswick black. Absolute cleanliness in vessels and liquids is essential to success. It is usually cheaper and more satisfactory to send the glass to a mirror-maker.

Size of Clock Dials.

Allow 1 ft. diameter for every 10 ft. from the ground, and then add 6 ins. to this; thus, if the dial is to be 40 ft. from the ground, the diameter should be 4 ft. 6 ins.

Wire Drawing.

Wire may be reduced in diameter or *drawn* by forcing it through holes in a piece of steel or other substance. A steel die is used where practicable, but for some purposes diamond dies are preferable. The diamonds used are either natural stones or chips from large stones used in jewellery. For a hole ·055 in. in diameter a 5-carat stone is needed, whilst stones weighing half-a-carat suffice for dies with holes from ·014 in. down to ·009 in. in diameter and under. In copper wire the smallest size made commercially is 0·002 in. in diameter. Thirteen diamonds are needed to reduce the wire from ·010 in. in diameter to 0·003 in. in diameter. Wires thinner than ·002 in. in diameter are exceedingly expensive to make. A lot drawn for exhibition purposes from ·0022 in. in diameter down to ·001 in. in diameter took 7 drafts. The life of the diamonds when drawing copper wire is six months to a year, provided the stones are of good size, hard, smooth, and well drilled. The weight produced per operator per day falls very rapidly as the size of the wire is reduced. Thus, whilst one man will produce 1,100 lbs. per day of No. 22 (B. and S. gauge), he can only draw 45 lbs. of No. 40 (B. and S.). Diamonds are also used for drawing steel, though they are not economical, nor do they produce a better quality of wire than steel die-plates; but if fine steel wire is wanted very round and true to size, the diamond dies seem necessary. A steel die will not keep to size for more than one coil of No. 33 wire or finer. The life of a diamond is much shorter on steel than on copper, averaging only about three days, when it must be polished out for the next larger size. The surface produced on steel wire is not so smooth when diamonds are used as it is with steel. The speed at which the wire is drawn appears to have little effect on the life of the diamond die, which depends solely on the length passed through. About 200 lbs. weight of steel wire can be drawn through a No. 32 (B. and S.) diamond die-plate before it is off size, 15 lbs. through holes ·005 in. to ·003 in. in diameter, and less than 1 lb. through holes smaller than ·002 in. in diameter. The smallest commercial size is ·0025 in. steel brush wire, drawn from low or medium carbon steel. Difficulty was at one time experienced in drawing hard music wire smaller than ·012 in. in diameter without breaking the diamond; but nowadays it can be drawn as small as ·005 in. in diameter, using 2 to 2½-carat diamonds for the dies. Below about ·009 in. or ·008 in. diameter, however, music wire becomes very curly, and no method of keeping it straight has yet been discovered.

Cracks in Metal.

A crack in a piece of metal is prevented from extending further by the well-known means of drilling a hole where the rent ends; but when the hole is not bored on just that spot the crack is apt to continue beyond the hole. To facilitate the search for the exact point, moisten the cracked surface with petroleum, then wipe it, and immediately rub it with chalk. The oil that has penetrated into the crack exudes, and thus indicates with precision where the crack stops. The best method of healing cracks is by electric or acetylene welding.

Rendering Celluloid Incombustible.

In order to overcome the undesirable quality of celluloid to ignite, it may be dissolved in a mixture of ether and alcohol and added to an ether-alcohol solution of ferric perchloride. The clear syrupy liquid is poured into a suitable vessel and is left for spontaneous evaporation. The resulting substance of shell-colour is, after washing and drying, a celluloid of great pliability and transparency, and is incombustible.

See also 'Celluloid,' by Dr. Bückmann· Fr. London, Scott, Greenwood & Son, 8 Broadway, Ludgate Hill, London, E.C. 4. Price 8*s.* 6*d.*

Wood-Worms in Oak

It is stated that the most effective means of treating oak work when attacked with wood-worm is to give it several coats of paraffin, well soaked into the wood. This should be done by a careful workman, making quite sure that every hole has been well soaked with the paraffin; the paraffin does not damage the oak, but has a tendency to improve the colour.

The extermination of the *Xestobium tessellatum* in the oak roofing of Westminster Hall has been effected by spraying the timber with a mixture of 50 per cent. tetrachlorethane, 6 per cent. cedar wood oil, 2 per cent. solvent soap, 2 per cent. paraffin wax, and 40 per cent. trichlorethylene. The tetrachlorethane is a perfect insecticide, but it is so dangerous that those who handle it must use gas masks.

Thermostatic Metal.

Thermostatic metal, manufactured by the *British Thomson-Houston Company, Ltd.*, in appearance a homogeneous metal, is formed of two metal strips having widely different coefficients of expansion. The two metals are welded together along their entire length, and are quite inseparable under normal working conditions. When the duplex strip is subjected to change of temperature, one half will expand more quickly than the other, causing the strip to bend. A change of one degree of temperature is said to affect its curvature to a measurable extent, and practically instantaneously. In bending, it exerts a force sufficient for the direct operation of levers, the opening and closing of ventilators, etc. The metal can be cut, stamped, or machined. it is supplied in various thicknesses from 0·015 in. to 0·25 in.

Setting a Spirit-Level Glass.

A simple method of setting a spirit level glass is to use a small piece of putty to support each end temporarily. The plastic putty can be made to hold the glass in the required position, it being an easy matter to depress either end so that it will be parallel or level with the working surface of the levelling bar. When properly levelled up in this way plaster of Paris is poured around the supporting ends of the glass and allowed to set. The glass will then be held permanently in place. (J. H. B., *Machinery*.)

Supporting Power of Ice.

Ice 1½ inches thick will support a man.
„ 4 „ „ „ cavalry and light guns.
„ 5 „ „ „ an 84-pound cannon.
Ice 10 inches thick will support a crowd.
„ 18 „ „ „ a railway train.

Removing Enamel.

The ordinary paint-removers, designed to remove air-dried paint and varnishes, are not adapted, or intended to be used, for the removal of baked enamel from metallic surfaces such as those of automobiles. It is customary in the removal of baked enamel, particularly enamel which is baked under high temperatures, to laboriously chip it off. D. F. Clark, of Harrisburg, Pa., has compounded a body (U.S. Patent No. 1,495,547) which may be applied with a brush, and which will adhere to the enamelled surface, and on allowing it to remain for from 15 mins. to 2 hours, depending upon the temperature at which the enamel was baked, the enamel may be easily brushed off. The best results are obtained from a mixture of the following ingredients in the proportions mentioned; 20 parts of methyl acetone; 20 parts of denatured alcohol; 10 parts of aqua ammonia (of 26° to 32°); 10 parts ammonia carbonate; 15 parts benzol; 10 parts xylol; 5 parts paraffin wax; 5 parts celluloid chips; 5 parts soap. The benzol, xylol, and methyl acetone are boiled, and the wax and celluloid are stirred in until thoroughly incorporated. The mixture thus far made is then permitted to cool. After cooling, the denatured alcohol is added. Finally, the ammonia is added. The purpose of the celluloid and the wax is to impart a viscous consistency to the mass and prevent evaporation of the volatile constituents. Some enamelled metals have so adhesive an enamel that this treatment will not remove it.

Flow of Sand.

The velocity of flow of sand and other fine materials through openings of various shapes and in different circumstances, is determined mainly by the size of the particles and of the opening, but is slightly diminished by angularity of the particles or by moisture on them. The specific gravity of the particles, the height of the material above the opening, and the shape of the upper contour of the material have little effect. If D is the diameter of the opening, d that of the particles, both in inches, the mean velocity of flow V in feet per second is given with sufficient accuracy for most practical purposes by the equation, $V = (D - 2d)/\sqrt{D}$.

(*Hersam: Journal of the Franklin Institute.*)

SECTION XLIII

RADIO COMMUNICATION

(Pp. 2821-2830.)

SECTION XLIII

RADIO COMMUNICATION.

(Contributed by the Editor of 'The Wireless World.')

Glossary of Technical Terms.

The following list of definitions contains terms that are usually unfamiliar to engineers who have not made any special study of radio technique. Expressions that have more or less passed into everyday language since the inception of broadcasting in this country have been omitted.

Amplification Factor (of a valve).—The ratio of the change of anode voltage necessary to bring about a given change of plate current, to the change in grid potential required to produce the same change in anode current. More simply, the number of volts by which the anode potential must be lowered to maintain the anode current constant when the grid potential is raised by one volt. It represents the maximum voltage amplification that the valve can theoretically provide.

Anode.—The electrode of a thermionic valve, which, when maintained at a higher potential than the cathode, attracts negative electrons from it, thus bringing about a current flow between the two.

Anode Bend Detection.—A method of rectification in which the grid circuit of a valve is so adjusted that the application of a given increase in oscillatory grid voltage will bring about an increase of anode current much greater than the decrease of this current due to a reduction in grid voltage by the same amount. The valve is operated on the lower bend of its characteristic curve by applying a suitable negative polarising voltage from a local source.

Astatic Coil.—An inductance wound in such a way that its external field is strictly limited, thus preventing magnetic interaction with other coils in close proximity.

Band-Pass Filter.—A network of coupled circuits arranged to pass a definite band of frequencies.

Beats.—When two wave motions of slightly dissimilar frequencies are superimposed, a pulsation is produced by the alternate coincidence and opposition of the waves. These pulsations or 'beats' have a frequency equal to the difference between the frequencies of the two superimposed wave motions. In wireless reception, the resultant frequency can be rectified and the principle applied in various ways.

Damping.—A term relating to the rate at which an oscillation dies away or decays, and also to the forces responsible for this progressive decrease in amplitude.

Detector.—In a wireless receiver, this term is applied to a device intended for converting incoming oscillations into unidirectional pulses of current. (See *Anode Detection* and *Grid Detection.*)

Diaphragm.—The sound-producing vibrating member of a loud-speaker or telephone receiver.

Eliminator.—An appliance comprising voltage-regulating, smoothing, and, if necessary, rectifying devices, and designed to provide the necessary anode, filament, or plate potentials for a wireless receiver from electric supply mains, whether A.C. or D.C.

Fading.—Should be applied exclusively to variations in signal strength due to changes in the reflecting properties of the Heaviside Layer, and not to changes brought about by alterations in transmitting power, etc.

Field Strength.—The intensity of the electric and magnetic field due to the radiation of a wireless transmitter at a given distant point. It is conveniently measured in terms of millivolts induced in an aerial having an effective height of a given number of metres, and is then expressed as ' millivolts per metre.'

Full-Wave Rectification.—A system of rectification in which both positive and negative half-cycles of an alternating current are used.

Ganged Controls.—An arrangement in which two or more controls of a wireless receiver (generally variable condensers) are linked together mechanically in such a way that they may be operated from a single control knob.

Grid.—The wire gauze or spiral wire electrode interposed between anode and filament of a valve, which controls the electron stream emitted by the filament.

Grid Detection.—A method of rectifying high-frequency oscillations, based on the unilateral conductivity of the grid-filament space inside a valve, and depending for its efficacy on use being made of the curvature of the grid volts/grid current characteristic. A small condenser is connected in series with the grid, and when the latter receives a negative charge, the value of anode current is reduced. This charge is allowed to leak away through a high resistance, in order that the grid may assume its mean operating potential before dealing with the next impulse.

Heaviside Layer.—It is generally assumed that the upper rarefied stratum of the earth's atmosphere is ionised ; it is in consequence a partial conductor of electricity, and therefore a reflector of wireless waves. This theory accounts for the transmission of wireless signals round the curvature of the earth, and also for such phenomena as ' fading ' and ' skip distances.'

High Frequency.—Generally applied to electrical oscillations of a frequency above the limits of audibility.

Indirect Ray.—Radiated waves deflected downwards from the Heaviside Layer (*q.v.*). The term ' direct ray ' is applied to radiation which reaches its destination *via* the earth's surface.

Metal Rectifier.—A power rectifier consisting of a contact junction between two dissimilar metals, as, for instance, copper with a film of copper oxide and lead. A number of such elements may be connected in series to deal with high voltages.

Motor-Boating.—A term of American origin applied to undesirable oscillations in a low-frequency amplifier, brought about by unwanted reaction effects between the various circuits. When an amplifier affected with this trouble is connected to a loud-speaker, a sound similar to the exhaust of an internal combustion engine is produced.

Neutralised Amplification.—A system of high-frequency amplification in which a tendency towards unwanted self-oscillation, due to interelectrode capacity of the valve, is balanced out by providing means whereby equal potentials of opposite phase may be passed back from anode to grid circuits.

Pentode.—A thermionic valve essentially designed for low-frequency amplification, and comprising five electrodes, including three grids. It has the advantage of a high amplification factor, and gives a very considerable power output with relatively low anode potentials.

Power Valve.—A type of low-frequency amplifying valve intended to provide a large power output from its anode circuit rather than to afford high voltage magnification.

Reaction.—An arrangement applied to a valve whereby part of the amplified oscillatory energy in its plate circuit is fed back to the grid circuit, thus allowing incidental losses in this latter circuit to be nullified, with the practical result that signal voltages are greatly increased. The extent to which this retroactive or feed-back effect may be applied is usually under control, so that it may be adjusted to meet the conditions under which the receiver is being operated.

Rectification.—Conversion of an alternating current into a unidirectional pulsating current. The term is applied both to low-frequency currents and to high radio-frequencies, but there is a tendency for the expression 'detection' to be allotted to the latter.

Rejector Circuit.—A tuned oscillatory circuit with its constants so arranged that it offers a very high impedance to oscillations of certain definite frequencies, while allowing others to pass readily.

Screen Grid Valve.—A valve designed exclusively for high-frequency amplification : a fourth electrode, generally in the form of a closely meshed grid, is interposed between the normal control grid and the anode, and acts as an electrostatic screen, reducing incidental capacity between these two electrodes. A positive polarising potential is applied to the extra grid.

Screening.—The provision of metal partitions so arranged that circuits carrying oscillatory currents cannot affect adjacent circuits.

Selectivity (of a wireless receiver).—The relative extent to which a receiver is capable of selecting one particular transmission to the exclusion of other frequencies corresponding to interfering radiation.

Side-Band.—The effect of modulation as applied to the carrier wave of a telephony transmitter is to produce a number of high-frequency oscillations with values above and below the actual frequency of the carrier wave, and in considering the width of the frequency spectrum occupied by a station, these additional frequencies must be taken into account.

Thermionic Valve.—Embraces the various valves with from two to five electrodes generally used in radio transmission and reception, and excludes gas-filled rectifying tubes. A modern valve comprises a cathode or filament (sometimes both, the filament being in the form of a heater element), at least one grid, and an anode, all being contained in a glass envelope, exhausted to the highest degree possible.

Triode.—A three-electrode thermionic valve.

Tuned Anode.—A simple form of intervalve coupling used in high-frequency amplification, in which an oscillatory circuit connected in series with the anode of the valve is tuned to act as a rejector of the frequency that is to be received.

Wavelength.—The distance at any given instant between the maximum positive points of two successive waves. Irrespective of their length, electro-magnetic waves travel with a velocity of three hundred million metres per second.

Useful Formulæ.

WAVELENGTH.—The wavelength of an oscillatory circuit is ascertained by applying the formula :

$$\lambda = 1884\sqrt{LC}.$$

In terms of frequency :

$$f = \frac{10^6}{2\pi\sqrt{LC}}$$

where

λ = wavelength in metres,
L = inductance in microhenries,
C = capacity in microfarads,
f = frequency in cycles per second.

CAPACITY.—Capacity of fixed condensers :

$$C = \frac{0{\cdot}0885\ A\epsilon\ (n-1)}{d}.$$

Reactance of a condenser :

$$\frac{1}{2\pi fC}$$

C = capacity in farads,
A = area of overlap of plates in sq. centimetres,
ϵ = dielectric constant of separating material (see below),
n = number of metal plates,
d = distance separating plates (in cms.),
f = frequency in cycles per second.

Dielectric constants of insulating materials in common use, as compared with air (air = 1)

Ebonite	2·56 to 3·48	Fibre	5·1 to 5·9
Glass	6·6 to 10	Mica	5·0 to 7·0
Shellac	2·95 to 3·73	Paraffin Wax	1·92 to 2·47
India Rubber (Para)	2·34	India Rubber (vulcanised)	2·94

Condensers in parallel:

$$C = C_1 + C_2 + C_3 + \text{etc.}$$

Condensers in series:

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \text{etc.}$$

INDUCTANCE.—The following formula gives the inductance of a single-layer coil with closely-wound turns:

$$L = \pi^2 d^2 n^2 l K,$$

where

L = inductance in microhenries,

d = diameter of coil (in cms.),

n = number of turns per cm.

l = length of coil (in cms.),

K = correction factor depending on ratio of diameter to length of coil (see following Table).

$\frac{d}{l}$	K	$\frac{d}{l}$	K	$\frac{d}{l}$	K
0·00	1·000	0·80	0·735	4·0	0·365
0·10	0·959	0·90	0·711	5·0	0·320
0·20	0·920	1·00	0·688	6·0	0·285
0·30	0·884	1·5	0·595	7·0	0·258
0·40	0·850	2·0	0·526	8·0	0·237
0·50	0·818	2·5	0·472	9·0	0·218
0·60	0·788	3·0	0·429	10·0	0·203
0·70	0·761				

Reactance of an inductance coil (in ohms):—

$$2\pi f L$$

where

f = frequency in cycles per second,

L = inductance in henrys.

H.F. AMPLIFICATION.—The maximum stage H.F. amplification attainable from a screen grid valve, without such adventitious aids to stability as neutralisation, is given by the following formula, which refers to a wavelength of 200 metres. Stability at higher wavelengths can, of course, be assumed.

$$A = \frac{-1 + \sqrt{1 + 2\mu R_o \omega C}}{\omega C_o R_o}.$$

Stage amplification obtainable with a transformer with ratio other than the optimum is given by:

$$A = \frac{N\mu R}{R + N^2 R_o}$$

A = stage amplification,

C_o = anode-grid capacity in farads,

μ = amplification factor of valve,

R_o = A.C. resistance of valve (in ohms),

R = Dynamic resistance of tuned circuit (in ohms),

N = Step-up turns ratio of transformer,

$\omega = 2\pi \times$ frequency (at 200 metres, $\omega = 10^6 \times 2\pi \times 1{\cdot}5$).

L.F. AMPLIFICATION.—Voltage stage amplification (approx.) of a transformer-coupled amplifier :—

$$\mu \frac{N_2}{N_1} \times \frac{X}{\sqrt{X^2 \times R_0^2}}$$

where

μ = voltage factor of valve,
N_2 = number of secondary turns,
N_1 = number of primary turns,
X = reactance of primary coil (in ohms),
R_0 = A.C. resistance of valve.

These tables give information necessary in designing high- and low-frequency inductance coils, etc. In the columns headed 'turns per inch run' and 'turns per sq. inch,' an average thickness of covering is assumed; there is not complete uniformity in this matter.

Empirical Formulæ.

FRAME AERIALS.—Provided a frame aerial is wound in a conventional manner, is of ordinary dimensions, and is shunted by a 0·0005 mfd. condenser, an inductance suitable for covering the 200–550 metres waveband is given if a total length of 80 ft. of wire is used.

Similarly, the use of 250 ft. of wire will provide an inductance suitable for covering the waveband 900–2,000 metres.

OPEN AERIALS.—The natural wavelength of a normal open aerial is from 4 to 5 times its length.

VALVE GRID BIAS.—For amplifying conditions, an approximation to the correct grid bias (in volts) is given by

$$\frac{\text{Anode voltage applied}}{\text{Amplification factor of the valve} \times 2}$$

For anode bend detection, the value ascertained by the above means is doubled.

Wavelength and Frequency Tables.

The use of these Tables, which give inductance/capacity values for radio frequencies, will be evident from the following examples:—

(*a*) Given a tuned circuit whose total capacity is 0·0003 microfarads and inductance 150 microhenries, what is its natural wavelength and its natural frequency?

The L.C. constant of the circuit is $0{\cdot}0003 \times 150 = 0{\cdot}045$, and the corresponding wavelength is found from the tables to be 400 metres, while the frequency is 750 kilocycles.

(*b*) What inductance will be required to tune a condenser of 0·0002 mfds. to 350 metres?

From the Table, L.C. for 350 metres is 0·03448; hence the inductance is 0·03448 divided by 0·0002, that is 172 microhenrys.

(*c*) A circuit with a natural frequency of 1,000 kilocycles is required, the inductance of the tuning coil being 127 microhenrys; what capacity should be connected across the coil?

L.C. for 1,000 kilocycles is 0·02533; hence the capacity is 0·02533 divided by 127, that is 0·0002 microfarads.

(L. is in microhenrys and C. in microfarads.)

Wave-length. Metres.	Frequency Kilocycles.	L.C.	Wave-length. Metres.	Frequency Kilocycles.	L.C.	Wave-length. Metres.	Frequency Kilocycles.	L.C.

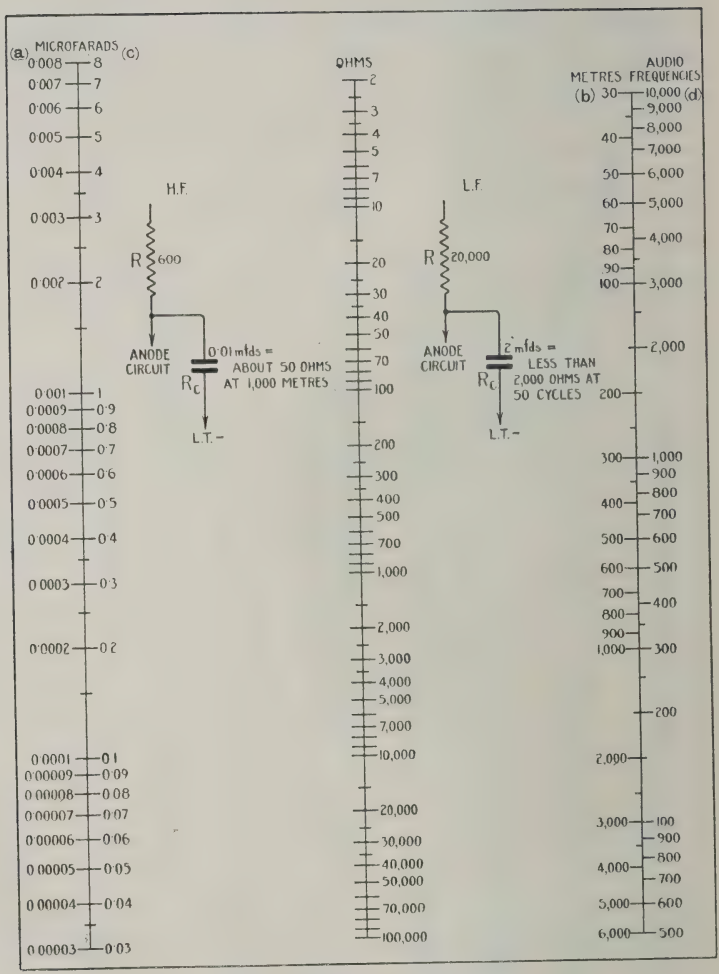
RESISTANCE AND CAPACITY CHART.

This ABAC gives resultant values of resistances in parallel or capacities in series.

The outer lines can be taken as representing Resistance values in units, tens, etc. of ohms, or Capacities in microfarads or fractions of microfarads, etc. By joining together the appropriate points on the outer lines, the resultant value can be read at the point of intersection with the centre line.



REACTANCE OF CONDENSERS AT RADIO- AND AUDIO-FREQUENCIES.

This chart is intended essentially for determining the relation between the Reactance of a Condenser and its associated Resistance as used in 'de-coupled' circuits. The low-capacity scale (*a*) is read in conjunction with the metres scale (*b*) for H.F. circuits and the high-capacity scale (*c*) with that giving Audio-frequencies (*d*). To read (*c*) in conjunction with (*b*) divide the ohms scale by 1,000. R should exceed ten times Rc.

ADDENDA.

Voltage amplification of a resistance-coupled L.F. magnifying stage is:

$$\mu \times \frac{R}{R + R_a}$$

where
R = external coupling resistance in ohms.
R_a = A.C. resistance (impedance) of valve.
μ = amplification factor of valve.

Formula for peak separation (in kilocycles) in a capacity-coupled filter.

$$\frac{\sqrt{\frac{1}{C_m^2\omega^2} - r^2}}{2\pi L}$$

where
ω = $2\pi \times$ frequency,
C_m = common coupling capacity in farads,
r = equivalent series resistance of the whole tuned circuit,
L = inductance of one filter coil in henrys.

To find equivalent diameter of ribbed coil formers, the overall diameter over ribs should be multiplied by the following constants:

No. of ribs	4	5	6	7	8	9	10
Multiply by	0·806	0·867	0·910	0·936	0·95	0·962	0·970

Power output (in milliwatts) of a valve is given by the formula:

$$KH\mu \left(\frac{V_a}{\mu}\right)^{\frac{5}{2}}$$

where H = a coefficient depending upon the ratio of external to internal impedance in the output valve. If there is no watts dissipation limit, H = 0·041, but with large power valves the load impedance may amount to 4 times the A.C. resistance of the valve, and H becomes a minimum of 0·032.

K = a constant obtained from the maker's valve curves:

$$\frac{I}{\frac{V_a}{\mu} - E_{if}}$$

V_a = anode voltage.
μ = amplification factor.

PATENTS, TRADE MARKS, AND DESIGNS

(Contributed by a Chartered Patent Agent.)

SECTION XLIV

PATENTS, TRADE MARKS, AND DESIGNS.

(Contributed by a Chartered Patent Agent.)

PATENTS.

Application for a patent must be made by the inventor or inventors either alone or in conjunction with one or more co-applicants or a limited company. By inventor is understood either the actual inventor or a person who first introduces an invention from abroad or to whom an invention is communicated from abroad.

When an application is made it is accompanied by either a 'provisional' or a 'complete' specification. In the former case the specification must describe the nature of the invention, but need not particularly describe the same, and the applicant has the right to use and publish the invention during nine months from the date of application, which time may be employed in perfecting the invention and in applying for foreign patents. This protection against the consequences of use and publication is known as Provisional Protection. Should a complete specification not to be filed within the prescribed period of nine months, the application is deemed to be abandoned, and no official publication of the provisional specification takes place. When the application is accompanied by a complete specification, full protection is obtained from the date of the acceptance, and between this date and that of the sealing of the patent the applicant has all the privileges and rights accorded by the patent, except that he will not be entitled to institute any proceeding for infringement, unless and until a patent for the invention has been granted.

When a provisional specification has been filed and it is not desired to abandon the application, a complete specification must be filed within nine months from the date of filing the provisional specification; one month's extension of this time, however, can be obtained on payment of a fee. In such a case the complete specification must describe substantially the same invention as that the nature of which is disclosed in the provisional specification; if not, the Comptroller may require the complete specification to be amended to avoid any disconformity between the two specifications.

A complete specification—whether filed with the application or after a provisional specification—must fully describe (if necessary with the assistance of drawings) the manner of carrying out the invention in practice, and at the same time clearly and correctly point out the features of novelty by a distinct statement of the invention claimed. The complete specification on being filed is submitted to an examiner who makes an investigation to ascertain whether the invention described therein has been wholly or in part claimed or described in any specification (other than a provisional specification not followed by a complete specification) published before the date of the application, and deposited pursuant to any application for a patent made in the United Kingdom within fifty years next before the date of the application, or in the complete specification of any prior application, although such complete specification may not have been filed when the application was made. If any anticipating specifications are found, the applicant will have the opportunity of amending the specification, and, if the amendment is not effected to the satisfaction of the Comptroller, the Comptroller may insert a reference to any of the prior specifications in the specification by way of notice to the public. Where the Comptroller is satisfied that the invention has been wholly and specifically claimed, he may refuse to grant a patent.

When an applicant has two or more provisional applications running concurrently and the subject-matter of such applications is of such a nature as to constitute a single invention which may properly be covered by one patent, the Comptroller may accept one complete specification in respect of the whole of such applications and grant a single patent thereon bearing the date of the earliest of such applications; in case of legal proceedings, however, the respective dates of the several applications may be considered.

Patents of addition for improvements in, or modifications of, an invention already patented may be applied for for any unexpired term of the original patent, and no renewal fees, other than those payable in respect of such original patent, will be payable.

Great Britain is a party to the International Convention for the protection of industrial property, under which an applicant for a patent in any one of the States being parties to the Convention may obtain priority in any of the other States—that is to say, an application may be made in any such States, notwithstanding that publication of the invention may have been made therein, providing that such application be filed within twelve months from the date of the original application.

When a complete specification has been accepted such acceptance is advertised, and the specification will be open to public inspection. Notice of opposition to the grant of a patent may be given at any time within two months from the date of such advertisement, but on the following grounds only, viz.:—

(*a*) That the invention was obtained from the opponent or from a person of whom he is the legal representative.

(*b*) That the invention has been published in the complete specification of a British patent filed in the United Kingdom within fifty years before the date of application for the patent, the grant of which is being opposed, or has been made available to the public by publication in any document (other than a British specification) published in the United Kingdom prior to the application.

(*bb*) That the invention has been claimed in the complete specification of a British patent which, though not published at the date of the application for a patent, the grant of which is opposed, was deposited pursuant to an application for a patent which is, or will be, of prior date to such patent.

(*c*) That the nature of the invention or the manner in which it is to be performed is not sufficiently or fairly described in the complete specification.

(*d*) That the complete specification includes matter not in the provisional specification, and forms the subject of an application made by the opponent in the interval between the leaving of the provisional and complete specifications.

(*e*) That, in case of an application under the International Convention, the specification describes or claims an invention other than that for which protection has been applied for in a foreign state or British possession, and that such other invention forms the subject of an application made by the opponent in the interval between the leaving of the application in the foreign state or British possession and the leaving of the application in the United Kingdom.

If there is no opposition, or, in case of opposition, if the determination is in favour of the grant of a patent, the Comptroller causes a patent to be sealed.

The decision of the Comptroller in most cases is subject to appeal to the Law Officer.

Letters patent extend to Great Britain, Ireland, and the Isle of Man, and are granted for sixteen years, subject to the payment of renewal fees commencing at 5*l.* in respect of the fifth year, and increasing 1*l.* for each succeeding year during the term of the patent, the last payment being 16*l.* These renewal fees are payable before the commencement of the year in respect of which the payment is made, but extensions of time for making these payments up to three months can be obtained, with the addition of a fine, and in the event of a patent lapsing through the non-payment of a fee, the Comptroller is empowered to revive the patent on certain conditions.

At any time after the sealing of a patent the Comptroller may, if requested by the patentee, cause the patent to be endorsed with the words 'licences of right' and any person shall then be entitled, as of right, to a licence under the patent upon such terms as, in default of agreement, may be settled by the Comptroller.

Furthermore, any person interested may apply to the Comptroller alleging that there has been an abuse of the monopoly rights under a patent and asking for relief. Such rights will be deemed to have been abused, if, after four years from the date of the patent, the invention—being capable of being worked in the United Kingdom—is not being worked on a commercial scale; or if such working is being prevented or hindered by the importation from abroad of the patented article; or if the demand for the patented article is not being met to an adequate extent and on reasonable terms; or if trade or industry is being prejudiced by refusal to grant licences, or by conditions attached by the patentee to the purchase, or use of the patented article or to the working of the patented process. If the Comptroller is satisfied that an abuse of the monopoly rights has been proved, he may order the patent to be indorsed with the words 'licences of right' and grant a licence to the applicant on such terms as he may think expedient; or he may order the patent to be revoked.

For 'PATENT SPECIFICATION DRAWINGS,' see page 90.

TRADE MARKS.

Trade marks are registered under the Trade Marks Act of 1905 as amended by the Act of 1919, which provides that a registrable Trade Mark must contain, or consist of, at least one of the following essential particulars:—

1. The name of a company, individual, or firm represented in a special or particular manner.

2. The signature of the applicant for registration or some predecessor in his business.

3. An invented word or invented words.

4. A word or words having no direct reference to the character or quality of the goods, and not being, according to its ordinary signification, a geographical name or a surname.

5. Any other distinctive mark; but a name, signature or word or words, other than such as fall within the descriptions in the above paragraphs 1, 2, 3, and 4, shall not be registrable under the provisions of this paragraph except upon evidence of its distinctiveness.

Provision is also made for the registration of any special or distinctive word or words, letter, numeral, or combination of letters or numerals used as a Trade Mark by the applicant or his predecessors in business before the 13th August, 1875, and which has continued to be used down to the date of the application for registration.

The Trade Marks Act of 1905 as amended by the Act of 1919 provides for a new kind of registration of Trade Marks whereby certain marks, not registrable under the principal Act, can now be registered, provided they have been in *bona-fide* use in the United Kingdom for not less than two years. For this purpose the Register is divided into two parts called Part A and Part B, the new kind of marks being registered in Part B.

An application for registration is made on a form bearing the necessary stamp and should be accompanied by four additional representations of the mark properly mounted. The application is then examined and the mark compared with other marks on record in the Trade Marks Office (this provision may be dispensed with in the case of application to register in Part B), and if, in the opinion of the registrar, any mark or marks be found having such resemblance to the mark sought to be registered as to be calculated to deceive, the applicant will be notified of the conflicting mark or marks, and if, within one month from the date of issuing such notice, no action is taken by the applicant the application will be deemed to be abandoned. Should, however, the applicant so desire, the registrar will appoint a hearing in order that the applicant may attend before him, when the registrar will decide whether the application can proceed. Appeal can be taken from the decision of the registrar to the Board of Trade.

When an application is allowed the mark is advertised in the Official Journal of the Trade Marks Office. The application is then open to opposition for one month from the date of the Journal in which the advertisement appears, and should no opposition be entered the registrar will, upon payment of the registration fee, issue his certificate of registration.

The term of registration of a Trade Mark is fourteen years and may be renewed.

DESIGNS.

For articles which do not form the subject of a patent, protection may in some cases be obtained by design registration where the novelty consists of shape, pattern or ornamentation. Copyright is granted for five years and is renewable for a further similar term, and it is within the discretion of the Comptroller of Patents and Designs to extend the term of a copyright for a third period of five years.

SECTION XLV

COST OF ENGINEERING WORKS

(Contributed by John T. Rea, Author of 'How to Estimate.')

SECTION XLV

COST OF ENGINEERING WORKS.*

(Contributed by John T. Rea, Author of 'How to Estimate.')

AERIAL ROPEWAYS.

Two broad types—Single-rope or Monocable, and Double-rope or Bi-cable. In the former the load carriers hang from and move with an endless hauling wire rope, for gradients up to 1 in 4; in the latter the load carriers hang from a fixed wire rope (double line), and are drawn along with an endless hauling rope, for any gradient.

Aerial ropeways fixed complete, including wire ropes, pulleys, carriers, wooden supports, engine, driving gear, machinery, labour, etc., to carry 10 or 20 tons per hour, in loads not exceeding 5 cwts. per carrier, and gradients as above, costs (1930):—

	Per Mile.
	£ £
Running single-rope system, to carry 10 tons per hour . . .	1,800 to 2,200
" " " 20 " . . .	2,700 " 3,300
Fixed-rope system (double line), to carry 10 tons per hour . .	3,000 ., 4,000
" " " 20 " . .	4,500 " 6,000

Prime Cost of Plant with Steel Structures.—The following table, by Mr. John H. Huntley, M.I.E.S., shows the pre-war standard amounts for aerial ropeways with no peculiar complications, using spiral construction ropes up to 20 tons capacity and locked coil ropes for 40 to 80 tons capacity, and represents the total cost of the plant erected. For lengths over 5 miles costs in proportion.

Capacity in Tons per Hour.	Length of Line in Miles.			
	½ Mile.	1 Mile.	2 Miles.	5 Miles.
Tons.	£	£	£	£
5 per hour . .	1,900	2,000	3,300	6,900
10 " . .	2,100	2,300	3,650	7,400
20 " . .	2,350	2,600	3,900	8,000
40 " . .	2,500	2,870	5,000	10,500
60 " . .	2,850	3,200	5,700	11,900
80 " . .	3,100	3,500	6,300	13,100

Working Costs per Day.—The following pre-war costs, by Mr. John H. Huntley, M.I.E.S., include depreciation, but exclude cost of driving, which varies extremely owing to the difference of height between stations, etc., and cannot be standardised.

Length in Miles.	Capacity per Day in Tons.					
	50 Tons.	100 Tons.	200 Tons.	400 Tons.	800 Tons.	1,000 Tons.
	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.
½ mile . .	17 6	21 0	25 0	32 0	42 4	48 0
1 " . .	19 5	24 0	28 10	37 7	52 0	58 5
2 " . .	26 6	31 6	36 4	49 7	68 10	76 10
5 " . .	45 7	51 0	61 0	83 3	126 0	156 10

* All prices mentioned are pre-war figures unless otherwise stated; present rates (1930) nearly double.

Aerial Ropeway at Loch Leven, Argyllshire (1906).—Erected for the construction of a dam for water-power purposes. Length of line about 4¼ miles. Arranged on the single-rope system, and has a mean gradient of 1 in 22·8, or a difference in altitude of 1,100 ft. against the loads. Three bends in the line, with a station at each bend, and including the power station and both terminals, there are six stations for loading and unloading. Eighty-six trestles, averaging 24 ft. high. Trestles, terminals, angle, and power stations of pitch pine. Driving power is from a Pelton wheel of 250 brake horse-power. Speed of line, 300 ft. per minute. Capacity, 700 to 1,000 tons per day, with 580 steel buckets, each having an individual load of 6 cwt., and spaced about 90 ft. apart. Twenty men are engaged in working the line. Total cost, including carriage, erection, and foundations, etc., complete, about 12,500*l.* or 2,600*l.* per mile.

Cost of operating per ton-mile, allowing for redemption in 3 years, labour and 10 per cent. on the labour account for supervision, was estimated at 2*d.*

Plant for Single-rope Fixed-grip System.—Prices vary greatly according to the ground passed over and the material transported, so the following figures are merely approximate. They are the rates for articles at manufacturers' works to which must be added the cost of packing and marking for export, about 4 per cent. overall, carriage, loading and unloading, and erection with concrete foundations, etc., as well as of motive power, which always differs. The value of timber structures would be about 15 per cent. less than that of corresponding structures in steel. From quotations received in August, 1922.

Description of Parts.	10 tons per 10 hrs.' line. £	25 tons per 10 hrs.' line. £	50 tons per 10 hrs.' line. £
1. Steel wire rope, trestle mountings, grips and carriers for a length not exceeding 1 mile—per mile	400	600	825
Ditto over 1 mile but not exceeding 3 miles in length—per mile	440	660	910
2. Driving and tension gears for a line not exceeding 1 mile	140	160	175
Ditto over 1 mile but not exceeding 3 miles in length	250	300	330
3. Mountings for each angle station giving any degree of deviation	70	80	90
4. Steel trestle structures, average about 16 per mile, height 20 ft., per trestle	18	22	20
5. Steel structures for terminal gears for a line not exceeding 1 mile	100	120	135
Ditto, ditto, for a line over 1 mile, but not exceeding 3 miles in length	160	180	200
6. Steel structures for angle stations, each	50	65	75

Example of Approximate Estimate.—To illustrate the method of estimating from the foregoing particulars the following example is given. The cost of a ropeway ¾ mile long to carry 25 tons per 10 hours with one angle station: steel trestles, and timber structures for terminal and angle stations. From quotations received in August, 1922:

	£	*s.*	*d.*
Steel wire rope, trestle mountings, grips, carriers, as No. 1—¾ of 600*l.* per mile	450	0	0
Driving and tension gears as per No. 2	160	0	0
Mountings for angle station as per No. 3	80	0	0
Steel structures for 12 trestles as per No. 4—22*l.* × 12	264	0	0
Timber structures for terminal gears as per No. 5—120*l.*, less 15 per cent. (18*l.*)	102	0	0
Timber structures for angle stations as per No. 6—65*l.*, less 15 per cent. (9*l.* 15*s.*)	55	5	0
	1,111	5	0
Packing and marking for shipment, 4 per cent.	44	9	0
Total cost of ropeway materials for ¾ mile	1,155	14	0

Add to the foregoing carriage, unloading, erection, foundations, and motive power.

ARTESIAN WELLS.

Artesian bored tube wells, including boring by the percussion, percussion hydraulic, or rotary methods, according to the sub-strata, supplying steel-socketed lining tubes with butt ends, flush-screwed, and special solid steel cutting shoe, and providing all materials, plant and labour, up to 100 ft. in depth; add 10 per cent. for every additional 10 ft. Telescoping the lining tubes

is obsolete, as they should be one continuous tier. Special sizes run up to 4 ft. and 6 ft diameter. See also 'Tube Wells,' p. 2887. Estimated costs (1930) :—

Soil.	Tubes.	Per ft. deep.
In easy soils, such as earth and sand	3 in. to 4 in. external diameter	15*s.* to 20*s.*
	6 in. „ 9 in. „ „	25*s.* „ 34*s.*
In soft rocks, such as chalk or shale	3 in. „ 4 in. „ „	20*s.* „ 25*s.*
	6 in. „ 9 in. „ „	32*s.* „ 42*s.*
In hard rocks, such as basalt or sandstone	3 in. „ 4 in. „ „	30*s.* „ 35*s.*
	6 in. „ 9 in. „ „	46*s.* „ 62*s.*

London.—The charges of the Metropolitan Water Board for domestic supply are based upon 5 per cent. of the rateable value of property, and in the case of a large building, such as business premises or a bank, are out of all proportion to the water used. Charges of 200*l.* to 600*l.* per annum are common, and even 4,000*l.* has been paid. Roughly speaking, any building owner in London paying more than £120 a year for water will find it better to sink an artesian well. Boreholes over 1,000 ft. deep have been sunk in the London basin, and yield 100,000 gallons per hour. The flow is reliable, the water is of a low temperature, pure and soft (generally about 5° of hardness compared with 16° of the Water Board supply), leaves no deposit on pipes and boilers, and the cost is very small.

The capital outlay for many important buildings in London for an independent water supply, including sinking an artesian well and providing the pumping plant, where the quantity runs from 1,000 to 4,000 gallons per hour, varies from 1,500*l.* to 4,000*l.*

The cost of pumping artesian wells depends on the lift and power required, and may be as low as ¼*d.* per 1,000 gallons on a lift up to 400 ft., and is commonly 1½*d.* per 1,000 gallons for manufacturing purposes. Pumping by electric motors, with current at 1½*d.* per unit, will work out to about 2½*d.* per 1,000 gallons when the water is raised some 300 ft. from the borehole to the storage tanks above. The capital invested in a separate installation would thus be repaid in three to six years, leaving only the pumping costs to be considered as an annual expense, so that the value of artesian wells is apparent.

BORING.

Percussion boring by the ordinary 'English' method to depths of 500 ft. costs 10*s.* to 20*s.* per foot, advancing 2 to 6 ft. per 24 hours.

Rope boring for oil, salt, etc., holes 6 to 15 ins. diameter, 20 to 60 ft. per day, costs 2*s.* to 8*s.* per foot. Plant for a hole 2,000 ft. deep weighs 80 tons, and costs about 2,000*l.*

Diamond boring in hard rock, 5 ins. diameter, costs in this country 8*s.* per foot down to 500 ft., and 12*s.* to 18*s.* down to 1,500 ft. Advance 5 to 10 ft. per day. Bort 'diamonds' are 2*l.* to 3*l.* per carat for the softer rocks, and carbon 6*l.* to 12*l.* per carat for the harder ones. Boreholes above 6 ins. diameter are thus almost prohibitive for expense.

Chilled shot method for relatively large boreholes, 6 in. diameter, in hard ground, costs 10*s.* to 12*s.* per foot. It is slower but cheaper than diamond boring, and consists of chilled steel shot fed into a thick steel pipe notched at the lower end and rotated upon the rock to be pierced, with water forced down.

Actual Costs—The following are from practical pre-war experience :—	Per ft. *s.*	*d.*
Rope boring at Middlesbrough, 8 ins. diameter, to depths of 1,000 ft., at rate of 60 ft. per day	8	0
Ditto. in Pennsylvania and Ohio, 6 to 15 ins. diameter, at rate of 20 ft. per day, average contract price	6	0
Diamond boring in Scotland, 5 ins. diameter, to depth of 1,800 ft., advancing about 6 ft. per day	6	4
Ditto. in British Columbia, 2,200 ft. deep, at rate of 10 ft. per day	8	6
Ditto. in Nova Scotia, 2 ins. diameter, sunk by the Government in fairly hard ground to depths of 200 to 400 ft. in 1913, averaged	9	0
Ditto. in Victoria, also sunk by the Government, averaged in the coal measures in 1912	9	3
Ditto. ditto. in the harder rocks	14	0
Chilled shot 6 in. Government boreholes in Nova Scotia in 1913, averaged	10	6
Some important boreholes of the world—		
Bezuidenville, Transvaal, 5,800 ft.	42	0
Czechow, Rybnik, Upper Silesia, 7,350 ft.	43	4
Paruschowitz, Silesia, 6,572 ft. (12 in. bore decreasing to 2½ in.)	11	6
Schladebach, Prussia, 5,737 ft.	21	2

BREAKWATERS.

Breakwaters formed of large rough blocks of stone as a foundation with heavy masonry walls above, forming a harbour. Average width 300 ft., and average depth 50 ft. below low-water mark. 150*l.* to 300*l.* per foot run complete.

Alderney.—Composite type of rubble mound and upright wall above. Mound terminates 12 to 15 ft. below low water. 338 ft. wide at base and 36 ft. at top. 90 ft. mean depth of water. 259*l.* per foot run.

Algiers.—Mound type, with large random concrete blocks surrounding the rubble. 50 ft. mean depth of water. 122*l.* per foot run.

Bizerta.—Composite type, with wall built on caisson system. 58 ft. mean depth of water. 60*l.* per foot run.

Colombo.—South-west breakwater, 1874–85, is 4,212 ft. long, built of concrete blocks weighing 18 to 30 tons, on the sloping bond system, and cost 705,200*l.*, or 167*l.* per foot run. Extension to ditto as a further protective arm, 1907–12, is 1,800 ft. long, also of concrete blocks, and cost 380,000*l.*, or 211*l.* per foot run.

North-east breakwater, 1894–7, is 1,100 ft. long, and constructed as a rubble embankment; the north-west or island breakwater, 1900–6, is 2,657 ft. long, and made of concrete; the two together cost 500,000*l.*, or 133*l.* per foot run.

Total length of the four breakwaters about 9,770 ft., with five lighthouses on them, and total cost 1,585,200*l.*, or an average of 162*l.* per foot run. Depth of sea, 30 to 36 ft. at low water. Rise of tide at Ceylon is only 2 ft. Engineers, Sir John Coode, Son, and Mathews.

Dover.—Wall type, composed of concrete blocks weighing 26 to 40 tons, 82 ft. wide at base and 40 ft. at top. Depth of water, 61 ft. high; 42 ft. low. 415*l.* per foot run.

Holyhead.—Composite type, with very predominant mound of rough rubble stone, 400 ft. average width at base and 40 ft. at top. Sea and harbour walls built upon the mound. 54 ft. mean depth of water. 163*l.* per foot run.

Marseilles.—Mound type. Outer casing of concrete blocks, 25 tons each, and average thickness 14 to 20 ft. Inner casing of rubble stone, 2 to 5 tons weight, about 12 ft. thick. Rubble hearting, ½ to 2 tons stones, and 6 ft. thick. 35 ft. mean depth of water. Joliette section, 72*l.* per foot run, and new section, 109*l.* per foot run.

Naples.—Composite type. 93 ft. mean depth of water. 186*l.* per foot run.

Plymouth (1811–48).—Rubble mound with walls on top, nearly a mile long. Slope of 5 to 1 seawards. 360 ft. wide at base and 43 ft. at top. Average depth, 45 ft. below low-water mark. Absorbed 3,670,440 tons of rubble and 22,150 cubic yards of masonry. Engineer, Sir John Rennie. 250*l.* per foot run.

Portland.—Mound type with large rubble blocks and heavy masonry wall above, 270 ft. wide at base. The largest of its kind in England and in two portions—inner about 2,000 ft. long and outer over 6,000 ft., with 400 ft. opening between them. Depth of water, 58 ft. high; 51 ft. low. 6 million tons of stone used. Convict labour. Total cost, 1,250,000*l.* 140*l.* per foot run.

Maintenance.—This is less for walls than for rubble mounds, as the latter are greatly affected by wave action, and need constant repair. Cost varies according to situation and exposure, and rarely exceeded 1*l.* per foot run per annum, pre-war. For some time it averaged 1*s.* 3*d.* at Holyhead, 7*s.* at Geneva, and 13*s.* at Naples.

(See Section XXVIII.)

BRIDGES.

Types.—(1) Arched, (2) Cantilever, (3) Girder or lattice, (4) Movable (bascule or lifting, rolling, swing, and transporter), (5) Pontoon (with barrels, boats, planks, etc.), (6) Suspension, (7) Trestle (with very high steel or wood framework piers), and (8) Viaducts or "land" bridges.

Costs include foundations, piers, abutments, approaches, footpaths, machinery, etc., complete.

Description.	Span.	Number of Spans.	Cost per ft. sup. (1930).
	ft. ft.		
Brick or masonry	50 to 100	Single	£2 to £4
	50 „ 100	Multiple	£3 „ £6
Ordinary concrete	30 „ 50	Single	£2 „ £3
	30 „ 50	Multiple	£3 „ £4
Reinforced concrete	50 „ 100	Single	£1 „ £2
	50 „ 100	Multiple	£2 „ £3
Steel bascule or lifting	50 „ 100	Single	£5 „ £8
	100 „ 200	Multiple	£8 „ £12
Steel trussed girder or lattice	50 „ 100	Single	£2 „ £5
	50 „ 100	Multiple	£3 „ £6
Steel suspension, with towers	50 „ 100	Single	£2 „ £4
	100 „ 200	Multiple	£4 „ £7
Steel swing, with pivot pier	50 „ 100	Single	£3 „ £5
	100 „ 200	Multiple	£5 „ £8

Brooklyn Bridge (1870–83).—Wire cable suspension bridge over the East River, connecting New York with Brooklyn. 5,990 ft. total length, including 1,596 ft. central span from tower to tower, two spans of 930 ft. from the towers to anchorage on either side, and the approaches of ironwork and masonry, 1,563 ft. on New York side and 971 ft. on Brooklyn side. Width 85 ft., divided into five passage ways for vehicles, trams, and foot passengers. Clear height above high water 135 ft. in centre and 118 ft. at towers, giving a free passage to shipping. Towers 277 ft. above high water, upon rock foundation 80 ft. below surface of river and 40 ft. beneath its bed. Supporting the spans are four cables nearly 16 ins. diameter, and 3,758 ft. long, with anchorages of solid stone masonry weighing 60,000 tons each, and rising 90 ft. above river's edge. Each cable contains 5,282 galvanised steel wires in 19 separate strands, of 278 lengths, and each strand has over 200 miles of continuous wire. Wires laid parallel, not twisted, with spiral wire wrapping. Deflection of cables between towers is 128 ft. Engineer, John A. Roebling. Total cost, including approaches, 3,100,000*l.*, or 518*l.* per ft. run, or 6*l.* per ft. sup.

Forth Bridge, Scotland (1883–90).—At South Queensferry, near Edinburgh. Steel latticework, with two main cantilever spans 1,710 ft. each, and 24 land spans, 42 to 688 ft. each. Each cantilever 690 ft. long, united by a girder 250 ft. span. The steel towers supporting the cantilevers are 361 ft. high, and the steel tubes of both are 12 ft. diameter at base, tapering to extremities. 50,960 tons of steel employed and 6½ millions of rivets. Complete length, 8,100 ft., and with approaches, 8,300 ft.; width, 30 ft.; 145 acres of surface to be painted. Double line railway. Height of railroad, 152 ft. above high water. Main piers of masonry, and concrete foundations in rock, 70 ft. below high water. Central pier of granite standing on the islet of Inchgarvie. Engineers, Sir John Fowler and Sir Benjamin Baker. Contractors, Sir Wm. Arrol & Co. Total cost, including approaches, 1,700,000*l.*, or 25*l.* per ft. run or 7*l.* per ft. sup.

Gôkteik Viaduct (1901).—In the Shan States, Upper Burmah, the viaduct forming part of the railway where it crosses a deep wide valley about 80 miles from Mandalay, and runs on to Kunlon at the Chinese frontier. The second most lofty steel trestle bridge in the world, but for combination of height, length, and weight of material easily the first. It is straight for 1,638 ft. at the centre, with terminal curves of 800 ft. radius, 341 ft. and 281 ft. long respectively. Total length between abutments, 2,260 ft. There are 15 trestles or skeleton towers, varying from 250 ft. to 320 ft. in height, 10 spans of 120 ft., and 7 spans of 60 ft., or 17 spans altogether, formed with lattice or plate girders. 5,000 tons of metal, and 200,000 rivets. All the metal parts, some 230,000 pieces, were prepared in the United States, shipped 10,600 miles, and transported 460 miles up country by the Burmah railway, where they were re-assembled and put up without a hitch. A single track was first laid, but space was left for a second when the traffic required it. Total cost, 61,000*l.*, or 27*l.* per ft. run, or 3*l.* 10*s.* per ft. sup.

Newcastle-Gateshead High-level Road Bridge (1924–28).—A combined single steel arch and suspension-bridge over the Tyne, forming a link in the Great North Road between Newcastle and Gateshead. It spans the river from bank to bank, 531 ft. length of actual crossing, being the longest arched bridge in Great Britain. The total distance of the roadway carried by channel steel hangers from the arch, together with the approach spans on either side, is 1,270 ft., and the complete weight 8,000 tons (including arch, 2,400 tons; deck of roadway, 1,600 tons; and approach spans, 4,000 tons). Masonry approaches, 581 ft. in addition. This great arch is of the two-hinged type, constructed of two mild steel trusses 45 ft. apart, with parabolic arched ribs and web members, 20 ft. maximum depth at centre. The arch was built out from both sides of the river simultaneously, and erected without any staging or supports from below, so as not to interfere with shipping. The foundations necessitated sinking heavy caissons, 84 ft. × 28 ft., to solid rock 70 ft. below ground level, each caisson containing 1,000 tons of concrete. The towers at either end of the arch are steel-framed buildings faced with granite, and may be used as warehouses. The approach spans were built up at the shore ends of the bridge and rolled forward into position, and are supported by octagonal steel columns 70 ft. maximum height, each standing upon a cast-iron cylinder, 21 ft. diam., filled with concrete and sunk to a firm bearing. The bridge road-way is 38 ft. wide, carries a double line of tramways and ordinary traffic, and two footpaths cantilevered to a width of 9 ft. on either side. It is designed to take exceptional loads of 100 tons on four wheels, and two 2 ft. diam. water mains and two 2 ft. gas mains are carried under the paths. The roadway is 93 ft. above high water, with 84 ft. clear headroom for vessels below, and the rise of arch is 170 ft. Engineers, Messrs. Mott, Hay and Anderson, with whom were associated Messrs. Coode, Fitzmaurice, Wilson and Mitchell. Architect, Mr. R. Burns Dick, F.R.I.B.A. Contractors, Messrs. Dorman, Long & Co., for whom Mr. Ralph Freeman, M.I.C.E., acted as consulting engineer, and Mr. Charles Mitchell as civil engineer. The contract was 571,225*l.*, but street improvements, acquisition of land and property, clearance of slums, etc., brought the total up to 1,150,000*l.*, of which the Ministry of Transport gave 60 per cent. Unit cost of bridge on contract price, with arch span and two approach spans or an overall length of 1,270 ft., came to 450*l.* per ft. run, or 8*l.* per ft. sup., including width of footpaths.

Newport Bridge, Mon. (1924–7).—Over the river Usk. Replaces an older stone and iron bridge of five arches and only 35 ft. total width, built in 1800, and widened in 1864. The new bridge, opened in June, 1927, is partly of reinforced concrete and stone, with five arched steel spans between four river granite piers with concrete hearting and two end abutments of stone backed with concrete. The piers are in cross pairs, built up on two rectangular caissons sunk by compressed air and filled with concrete, the space between each pier being bridged by a semi-

circular cross arch, 41 ft. 6 ins. diameter, leaving the old pier foundation undisturbed but eventually protected with concrete. Length of bridge from face to face of abutments is 357 ft., with a 36-ft. carriage-way and two footways each 12 ft. wide, making an overall width of 60 ft. between the cast-iron parapets. The concrete roadway and stone-flagged footpaths are carried in each of the five spans by decking plates on seven steel arched ribs, 8 ft. 6 ins. apart, the paths being cantilevered outwards from the face rib on each side. The bridge carries gas and water mains, electric and post-office cables, and twelve bronze lamp standards. Engineers, Messrs. Mott, Hay, and Anderson, conjointly with the borough engineer, Major W. E. Lloyd, M.I.C.E., and the resident engineer, Mr. G. L. Groves. Contractors, Sir Wm. Arrol & Co. Contract price, including demolishing the old bridge, was 140,275*l.*, or 393*l.* per ft. run, or 6*l.* 11*s.* per ft. sup.

Niagara Suspension Bridge (1852–5).—Connects the United States with Canada. A wire-rope suspension bridge for road and railway, with a single span of 821 ft., centre to centre of piers and 245 ft. above the water. Superstructure is a hollow rectangular box, 24 ft. wide × 18 ft. deep, on the top of which the railway is laid, while the bottom forms a roadway for public traffic, both floors being constructed of timber beams, etc. Railway floor is suspended from two wire cables, 10 ins. diameter, at intervals of 5 ft., and the lower floor by two similar cables. 120 stays. Two masonry towers at each end of the bridge, 60 ft. high, 15 ft. square at base, tapering to 8 ft. square at top, and pierced by an arch. Anchor chains embedded in masonry 7 ft. × 3 ft., and 25 to 35 ft. deep. Engineer, John A. Roebling. Total cost, 80,000*l.*, or 97*l.* per ft. run, or 4*l.* per ft. sup. This suspension bridge was replaced by a steel arch bridge in 1897.

Tower Bridge, London (1890–4).—Steel, with two fixed shore suspension spans 270 ft. each, and a lifting central span of 200 ft. Two large steel towers encased with stone, with two bascules or drawbridges in the centre and connected at top by a high-level footbridge, 140 ft. above high water. Bascules weigh 1,000 tons each, and are raised and lowered by hydraulic machinery which is contained in the chambers of the piers supporting the towers, each pier being 180 ft. long × 70 ft. wide. Staircases and hydraulic lifts are provided in the towers for foot passengers crossing the high-level bridge when the bascules are raised for the passage of shipping. Complete length, with approaches, 2,980 ft. Width of fixed spans between parapets, 60 ft., and breadth across centre span 50 ft. Engineer, Sir John Wolfe Barry. Sir Horace Jones, the City Architect, designed the architectural details. Contractors: Sir John Jackson for foundations; Sir Wm. Arrol & Co. for steelwork; and Sir W. G. Armstrong & Co. for hydraulic machinery. Total cost, including machinery and approaches, 903,000*l.*, or 303*l.* per ft. run, or 5*l.* per ft. sup.

Suspension Bridges.

Estimated costs by a well-known firm of steel manufacturers of strong steel wire rope suspension bridges of large power, designed to carry 15-ton traction engines with wagons in line on the bridge floor, the prices being for the whole of the iron and steel work, including lattice piers surmounted by cast-iron saddles for the ropes to run over, all bolts and nuts, holding down bolts, steel rod suspenders, open-steel parapets, high tension steel cables, steel cross girders to support decking, steel wind ties under floor, etc., ungalvanised but painted two coats before despatch, delivered f.o.b., London or Liverpool, or to railway stations in England; supplied only, and exclusive of timber floor, foundation work, and erection. Pre-war rates. If a concrete or asphalt floor is required the prices will be subject to an increase, owing to the additional strength necessary and the greater weight put on the structure. The span is centre to centre of piers, and the feet super. for area unit price, have been reckoned accordingly.

Span.	Width.	Area.	Total Price.	Price per Foot Super.	Weight of Steelwork.
Ft.	Ft.	Ft. Sup.	£	*s.* *d.*	Tons.
50	19	950	565	11 11	31
75	19	1,425	785	11 0	44
100	19	1,900	945	9 11	53
125	19	2,375	1,115	9 5	60
150	19	2,850	1,275	8 11	66
175	19	3,325	1,430	8 7	75
200	19	3,800	1,575	8 3	81
225	19	4,275	1,740	8 2	91
250	19	4,750	1,880	7 11	100
275	19	5,225	2,065	7 10	110
300	19	5,700	2,230	7 10	118

The prices may therefore vary from about 8*s.* to 12*s.* per ft. sup. If erected complete, including timber floor and concrete, stone, or brick foundations or abutments, and anchorages, the costs would be at least double the foregoing. Narrower bridges, down to 3 ft. wide, for lighter loads, such as foot traffic, cattle, mules, horses and carts, would be of reduced construction and correspondingly cheaper.

Actual costs of steel wire-rope suspension bridges, delivered and erected, including steel piers, wire-ropes, suspension bands, and timber for floor, but exclusive of any foundation work or anchorages. Pre-war rates. The span is centre to centre of piers, and the feet super. for area unit cost have been reckoned accordingly as before.

Locality.	Load.	Span.	Width.	Area.	Total Cost.	Cost per F.S.
		Ft.	Ft.	Ft. Sup.	£	*s. d.*
Bournemouth, across Alum Chine	Donkey carts and bath chairs	230	6	1,380	590	8 7
Derby sewage works	Foot traffic	86	3	258	165	12 9
Dryburgh, across the Tweed, near Melrose Abbey	Foot traffic	260	6	1,560	405	6 11
Linley, over the Severn. Two approach spans in addition, making a total span of 390 ft.	A row of 10-ton carts	213	12	2,556	1,700	13 3
Llandilo	Foot traffic	144	5	720	220	6 1
Llangollen	Foot traffic	146	3	438	190	8 8
Rhayader, for the Birmingham Corporation Waterworks	Cart traffic	110	10	1,100	450	8 2
Shrewsbury. Two approach spans of 30 ft. each in addition, making a total span of 210 ft.	Light vehicular traffic	150	8	1,200	950	15 10
Swalwell, over the Derwent	Foot traffic	125	4½	562	285	10 2
Warrington	Foot traffic	183	6	1,098	430	7 10
Wrexham, across the Dee.	Row of loaded haycarts	130	10	1,300	670	10 4

The average rate was therefore about 10*s.* per ft. sup. If erected complete, including foundation work and anchorages, the costs would be at least double foregoing.

Bridges of Concrete.

Coulouvrenière Bridge, Geneva (1895–6).—Across the Rhone, 351 ft. wide, and total length of bridge over the abutments 492 ft. Width between parapets 61 ft. 4 ins., two footways 12 ft. 6 ins. each, with a carriageway 36 ft. 4 ins. between the kerbs. Two large arches with spans 131 ft. 3 ins., and rise of 17 ft. 6 ins. Arches 3 ft. 3 ins. thick at both springings and centre, about 4 ft. 6 ins. at the haunches, and steel pivoted. Two smaller arches, 35 ft. 5 ins., and 39 ft. 4 ins., but are not pivoted, being elliptical. Very handsome bridge. Arches, spandrels, 9 spandrel walls, 2 ft. thick, 12 in. top table, and filling, all of concrete, 1 to 4½, 6, 7, and 8. Piled abutments. Facing of spandrel walls, columns, cornice, and parapet of stone. Wooden centres were used, with sand boxes for adjusting and striking. Total cost, 68,000*l.*, or 138*l.* per ft. run, or 2*l.* 5*s.* per ft. sup. of roadway and footpaths. Cost per cubic yard, including centering and scaffolding, was 3*l.* 2*s.* 3*d.*

Eyach Bridge, Hohenzollern (1895).—Designed by Herr Max Leibbrand, of Sigmaringen. A single span of 98 ft. 5 ins., with a rise of 9 ft. 10 ins. Concrete arch and table, 1 to 7½, and foundations to abutments, 1 to 9, which are piled. Pivots or joints made of granite instead of iron or lead. Bridge is 143 ft. long, 12 ft. 6 ins. total width, with roadway 7 ft. 6 ins. wide, and each footpath 2 ft. 6 ins. The footpaths overhang the arch on either side and were formed of old iron rails. Plain iron railing as parapet. Cost, 900*l.*, or 6*l.* per ft. run, or 10*s.* per ft. sup.

Kirchheim Bridge, Württemburg (1897).—Over the Neckar, which is 361 ft. wide at this point, with 230 ft. of foreshore, or a total of 591 ft. Designed by President von Leibbrand, chief engineer to the State of Württemburg. Length of bridge from outside to outside of abutments, 592 ft., and space between parapets 17 ft. 8 ins., including road, 12 ft. 8 ins., and two footways, 2 ft. 6 ins. each ; open iron parapets. Four spans of concrete arches, 124 ft. 8 ins. each, with a rise at the centre of 18 ft. Thickness of arch at crown, 2 ft. 8 ins., increasing to 3 ft. at springing. Concrete piers 7 ft. 6 ins. thick at springing level, faced with stone at water level ; cutwaters also faced with stone. Concrete in arches and abutments, 1 to 7½, spandrel walls, tables, etc., 1 to 9, and foundations for piers, 1 to 4. Concrete on face was tooled and coloured, and concrete in piers rendered 2 ins. thick with 1 Portland cement and 2 sand. Lead joints in the centres and springings of arches 6 to 7 ins. wide, bedded and recessed in stone. Screw jacks were used for striking the centres in place of folding wedges or sand boxes. Cost, 7,000*l.*, or 12*l.* per ft. run, or 13*s.* 5*d.* per ft. sup. of bridge table. Approaches, 2,250*l.* in addition.

Munderkingen Bridge, Württemburg (1893).—Over the Danube. Designed by President von Leibbrand. One span only of 164 ft., and rise 16 ft. 5 ins. Thickness of arch at centre 3·28 ft., at springing 3·61 ft., and at haunches 4·26 ft. The first concrete bridge where steel pivots on bearing boxes were used, one set at each abutment and one set at the crown. Internal and external spandrel walls, abutments, horizontal and intermediate tables, cornice, and arch itself, were of concrete, 1 to 7½, and tinted. Spandrel face of limestone, and ornamental open iron parapet. Cost of bridge, including piled abutments, 3,600*l.*, or 21*l.* per ft. run, or 13*s.* 6*d.* per ft. sup. of road and footway surface. Approaches, 1,000*l.* in addition.

Neckarhausen Bridge, Hohenzollern (1900).—Over the Neckar. Designed by Herr Max Leibbrand, of Sigmaringen. The handsomest concrete bridge in Germany, the concrete being coloured, and no stone used. A single concrete arch of 164 ft. clear span, with a rise of 15 ft. Arch ring 2 ft. 10 ins. thick at the centre, 3 ft. at the springing, and 4 ft. at the haunches. The arch is tapered on plan, being 1 ft. 8 ins. wider at the springing than at the centre. Concrete spandrel columns and arches over, instead of solid spandrel walls and haunches, thus reducing both material and dead load. Arches pivoted with steel pins and cast-iron brackets or bearings, and those carrying roadway were strengthened with iron rails built into the top and abutments. Concrete in arch 1 to 7½, faced with ⅝-in. spalls of limestone. Voussoirs, cornice, etc., were coloured. Width of macadam roadway 13 ft., and overhanging footpaths 2 ft. 6 ins., which is a cheap method. Centering was supported on temporary piles, with screw jacks for striking. Cost, 3,000*l.*, or 17*l.* per ft. run, or 19*s.* 5*d.* per ft. sup. Long approaches, 5,000*l.* in addition.

BRIDGES OF REINFORCED CONCRETE.

Spans, 50, 75, or 100 ft. External width, including parapets, 25 ft. Height, from mean water level to underside of eliptical arch, 13 ft. 1*l.* to 3*l.* per ft. sup. (1930).

Items.	Estimated Cost (1930).		
	50 ft. Span.	75 ft. Span.	100 ft. Span.
	£	£	£
Excavations	140	220	370
Concrete	500	930	1,336
Centering	260	480	680
Reinforcing Steel	210	390	556
Preliminaries 10 per cent.	110	200	294
Contractors' Profit, etc., 15 per cent.	180	330	484
Total Cost	1,400	2,550	3,720

Alexandra Bridge, Pietermaritzburg (1914–15).—Reinforced concrete on the Kahn system, 170 ft. long × 30 ft. wide between the parapets, with two 5-ft. footpaths cantilevered over a 20-ft. roadway. Central arch 75 ft. span, and a half arch 38 ft. span at each end. Cost, including 5 per cent. for designs and supervision, 5,906*l.* for the bridge and 4,008*l.* for the approaches = 9,914*l.* total. 52*l.* per ft. run, or 2*l.* per ft. sup.

Brivio Bridge, Italy (1913–17).—Over the river Adda, and gives access to the railway station of Cisano Bergamasco. Entirely constructed of reinforced concrete, 444 ft. long and 30 ft. wide, with a 24 ft. roadway flanked by two raised footpaths, each 2 ft. 7 ins. wide, with edges of L irons. The roadway is about 26 ft. above the average level of the river, and suspended from three reinforced concrete arches overhead. Span of centre arch 177 ft., and of side arches 144 ft., all being supported on two massive concrete pillars and shoulders, each 43 ft. × 13 ft., built on a group of 48 steel-shod concrete piles made on the Considère system, 14 ins. square, and driven 43 to 53 ft. through the bed of the river by a steam hammer weighing 4 tons. Normal load on each pile averages 35 tons, uniformly distributed by a superimposed concrete slab 3 ft. thick. Foundations protected by pitch pine shuttering 5 ins. thick. Sole of roadway 5 ins. thick, covered with asphalt and a layer of concrete and gravel on top, with 12 in. × 30 in. transverse beams underneath attached to 11 in. × 24 in. vertical bars and to 18 in. × 40 in. longitudinal external beams. Cast steel rollers for expansion. Parapet is of cast ironwork. Bridge designed to carry a double-track electric tramway, a steam roller of 22 tons, and a dense crowd of people calculated at 10 cwt. per square yard. Total cost, 20,000*l.*, or 45*l.* per ft. run, or 30*s.* per ft. sup.

Chatellerault Bridge, France (1900).—Across the river Vienne, and is formed entirely of ferro-concrete on the Hennebique system. Centre span 164 ft. and two side spans 135 ft. each, with rises of respectively 16 ft. and 13 ft., and a width between the parapets of 26 ft. 3 ins., excluding two cantilevered footways which overhang 3 ft. 5 ins. Spans of four arched concrete ribs, 35 ins. deep × 19 ins. wide at springings, tapering to 9 ins. square at the soffit, and extrados connected together by an arched table. Roadway and footpaths supported by spandrel pillars, 8 ins. square, and longitudinal concrete beams, the top table being 10 ins. thick at the centre, tapering to 5 ins. at kerb. The bridge only weighs 250 lbs. per ft. sup. Cost, 8,000*l.*, or 18*l.* per ft. run, or 12*s.* 6*d.* per ft. sup.

Loughor Bridge, Glamorganshire (1920–23).—Spans the tidal estuary of the river Loughor, and replaces the old timber trestle structure. The new bridge is of reinforced concrete, from a design by Messrs. L. G. Mouchel and Partners, carried out by the Yorkshire Hennebique Contracting Co., Ltd. Length, 720 ft. between the abutments, divided into 18 spans of 40 ft. each. Width, 36 ft. between the parapets, providing two footways, 5 ft. wide, and a carriage-way of 26 ft. between the kerbs. Piers rest on reinforced concrete piles, 15 ins. square, driven into the bed of the river to various depths of 5 ft. to 37 ft. Four piles to each pier, each pile being encased in a reinforced concrete cylinder, 1 ft. 9 ins. diameter, cross-braced with reinforced concrete tie-beams, 10 ins. × 14 ins. Main longitudinal beams, 12 ins. wide × 2 ft. 8 ins. deep in the centre; secondary beams, 7 ins. × 18 ins. Four main or longitudinal beams and 12 secondary or cross beams to each span. 5½ ins. reinforced concrete decking, covered with 2 ins. cushion of sand and finished with 4 ins. of 'Tarmac' roadway. Ducts, 18 ins. × 9 ins., left under footpath concrete flagging to accommodate electric cables. Parapet of pierced concrete panels, with moulded handrail. Abutments have reinforced concrete wall supporting the ground behind. Steel reinforcement was of plain round steel bars, $\frac{5}{16}$ in. to 1⅛ in. diameter, and the bridge was built in half-widths, so as not to interrupt the traffic. It was designed to carry a normal working super. load of 120 lbs. per square ft., and a rolling load of 48 tons. Total cost, excluding approaches, 56,700*l.*, or 79*l.* per ft. run, or 2*l.* 2*s.* 7*d.* per ft. super.

Pontypridd Bridge (1908).—Over the river Taff. Reinforced concrete on the Hennebique system, with the two piers on reinforced concrete piles. Total length 170 ft., and width 30 ft. Central river span 117 ft. Total, 3,600*l.* 21*l.* per ft. run, or 14*s.* per ft. sup.

Terralba Bridge, Italy (1916).—Part of a scheme for enlarging the Genova Brignole Station. It replaces about 600 ft. of the Terralba highway connecting St. Martino with St. Fruttuoso. Total length of bridge, including approaches, is 750 ft.; width 45 ft., including two footways each 5 ft. wide. Constructed of reinforced concrete and has six spans, four of 61 ft. and two of 58 ft., each span being built in three bays across. Part of the inclined approach was also formed in six spans, each of 35 ft. and three bays across, the remainder of the plane being constructed of massed work between supporting walls. Subsoil was a deep bed of soft, marshy clay, which prohibited piling and required a specially light foundation formed by 1 per cent. reinforced concrete rafts, the reinforcement being carried up into the pillars of the bridge. The rafts were supported on two pinewood piles per square yard, each 20 ft. long by 10 ins. wide, and tops coated with cement. Volume-ratio of reinforcement in superstructure was 1·8 per cent. to the gravel concrete. Total cost, 18,000*l.*, or 24*l.* per ft. run, including approaches, or 12*s.* 5*d.* per ft. sup. of concrete, including the foundation, and 6*s.* 8*d.* per ft. sup. of road and footpath.

Warrington Bridge (1913).—Over the river Mersey. Largest single-span reinforced concrete bridge in England, on the Considère system. River walls and abutments also of reinforced concrete. Clear span 134 ft., width 80 ft. between parapet walls, and ten parabolic ribs supporting upright and cross beams on which rest 6½ in. floor slabs. Roadway has wood-block paving, and footpaths have concrete slabs. Total cost, including approaches, 24,000*l.* or 34*s.* per ft. sup. ditto.

CANALS.

The total length of canals for inland navigation in the United Kingdom is 4,673 miles (3,641 in England and Wales, 184 in Scotland, and 848 in Ireland). 1,144 miles are owned by the railway companies, and 219 controlled by them. An ordinary inland canal in this country is 25–30 ft. wide at bottom, 40–45 ft. wide at water level, and 4–5 ft. deep. Canal boats are 70–75 ft. long and 7–8 ft. wide; barges are about the same length, but double the width, *i.e.* 14–15 ft. For maps and towns, etc., see the *Handbook on Canals*, with map, issued by the Canal Control Committee (Board of Trade), and obtainable from H.M. Stationery Office, Kingsway, London, W.C. 2, price 6*d.* net, or 8*d.* post paid. (November, 1918.) Total paid-up capital was 47,550,000*l.*, and the cost varied from about 5,000*l.* to 20,000*l.* per mile.

In 1905 the constructional cost of new canals in Great Britain, 40–45 ft. wide at bottom, 80–85 ft. wide at water level, and 8 ft. deep in centre, with locks 230 ft. × 22 ft. and 6½ ft. draught of water over sills, suitable for two lighters of 250 tons carrying capacity, was estimated at 30,000*l.* per mile. The cost of improving existing routes to reach the same standard was similarly reckoned at 15,000*l.* per mile. New barge canals would now cost (1930) 50,000*l.* per mile.

In France, in 1870, there were 3,000 miles of canals and 2,000 miles of canalised rivers. The average cost of the French canals up till then was 11,600*l.* per mile, and of the canalised rivers, 4,800*l.* per mile. Present length, 7,500 miles.

BARGE OR BOAT CANALS.

Basingstoke Canal (1794–96).—From Basingstoke, Hampshire, to the river Wey Junction Canal, Surrey. Length, 37 miles, including 29 locks. Total cost, constructional works only, 170,000*l.* or 4,600*l.* per mile.

Bridgewater Canal (1759–61).—In Lancashire; originated by the Duke of Bridgewater to bring coal from his mines on the Worsley estate to Manchester, but it was later extended to the Mersey. First length was only 10 miles, but complete length 38 miles. 50 ft. wide and 5½ ft. deep, with vertical stone walls instead of banks. The Barton aqueduct carried the canal over the river Irwell, at a height of 39 ft. Engineer, James Brindley. (The Bridgewater Canal was purchased by the Manchester Ship Canal Co. in 1887.) Total cost, constructional works only, 235,000*l.*, or 6,180*l.* per mile.

Dortmund and Ems Canal (1890–1900).—From Dortmund to the North Sea at Emden. Part of the 157 miles total length includes canalisation of the river Ems. Bottom width, 59 ft., 98 ft. at water level, and depth, 8 ft. Works include 1 canal lift, 3 masonry aqueducts, 185 bridges, and 20 masonry locks, 220 ft. long each. Artificial canal portion cost 29,000*l.* per mile, and river canalisation portion, 14,000*l.* per mile. The locks were 15,000*l.* each, and the weirs 8,500*l.* each. Total cost, 3,970,000*l.*, including 400,000*l.* for land.

Cost per mile of total length, including land	. . . .	25,286*l.*
,, ,, ,, ,,	constructional works only . .	22,740*l.*

Grand Junction (begun, 1790).—From the Oxford Canal at Bramston, Northamptonshire, to the Thames at Brentford, Middlesex. Width at bottom, 24 ft., and 36 ft. at water level. The main line is 93 miles long, but the total length, with branches, is 140½ miles (189 by Whitaker). Cost per mile, including land, etc., 19,500*l.*

Ulster Canal (1826–41).—Unites Lough Neagh with the upper Lough Erne, and extends from Charlemont, Co. Armagh, on the river Blackwater (which is navigable from Charlemont to Lough Neagh), passes Caledon, Monaghan, and Clones, and joins Upper Lough Erne, Co. Fermanagh, near Belturbet. Length, 47 miles. Total cost, constructional works only, 200,000*l.*, or 4,255*l.* per mile.

Worcester and Birmingham Canal (1791).—Connects these towns, and joins the Severn at the former. Runs through a tunnel 500 yards long, and three shorter tunnels. All are 18½ ft. wide, 7 ft. deep, and 18 ft. high. Length, 30 miles. Original cost per mile, 20,000*l.*

Irrigation Canals.

For irrigating large tracts of land for growing cotton, rice, sugar, wheat, etc., especially in America, Australia, Egypt, and India. The cost varies according to geographical features, nature of ground, available water supply, size of main canal, number of branches, distributing channels, and subsidiary works. In India the costs are approximately—

5,000*l.* to 10,000*l.* per mile of canal and main branches.
2*l.* to 3*l.* per acre of land irrigated.

Agra Canal (opened 1874).—In India, and draws its water supply from the Jumna at Okhla, ten miles below Delhi, irrigating 380,000 acres. The main and branch canals total 110 miles, and the distributing channels 600 miles. Total cost, including all works, 800,000*l.*

7,270*l.* per mile of canal and main branches
2*l.* 2*s.* per acre of land irrigated.

Cavour Canal (begun 1862).—In Italy, and starts from the river Po, not far from Turin, and terminates in a junction with the river Tessin above Novara. Length, 51 miles, with a total fall of 71 ft. The summer discharge of the Po being found insufficient, a branch canal was constructed for bringing a supplementary supply from the Dora Baltea, which rises from the glaciers of the Alps and possesses a large discharge in the summer when the Po is low. Total cost, 4,104,000*l.*, or 80,470*l.* per mile of main canal.

Ganges Canal (opened 1854).—The largest irrigation work in India, and waters the district between the Ganges and the Jumna. Designed by Sir Proby Cautley. The canal with its main branches is about 650 miles long, and can irrigate an area of 1,205,000 acres. It was remodelled about twelve years later. Total cost up to 1878 was 3,055,000*l.*

4,700*l.* per mile of canal and main branches.
2*l.* 11*s.* per acre of land irrigated.

Lower Ganges Canal (1870–90 approximately).—An extension to supplement the original foregoing canal. Designed for a total length of 582 miles. Irrigates 2,500,000 acres. Total cost about 4,500,000*l.*

7,730*l.* per mile of canal and main branches.
1*l.* 16*s.* per acre of land irrigated.

Upper Swat Canal.—In India, along mountainous country at the Malakand hills. Length, 150 miles, and irrigates 450,000 acres. Works include a tunnel, 11,235 ft. long by 18 ft. wide and 13 ft. high, seven shorter tunnels totalling one mile, 167 aqueducts across ravines, 20 to 100 ft. deep, a weir 700 ft. long, stop-dam, pitched channel, etc. Total cost about 1,300,000*l.*

8,670*l.* per mile of canal and main branches.

2*l.* 18*s.* per acre of land irrigated.

Ship Canals.

Large waterways as formed for ocean-going shipping, complete with channels, locks, docks, machinery, entrance breakwaters, etc.; construction works only, and excluding promotion, purchase of land, compensation, or legal charges:

100,000*l.* to 500,000*l.* per mile of actual canal.

Amsterdam Canal (1865–76).—Connects Amsterdam and the Zuyder Zee with the North Sea *via* Lake Y and Wyker Meer, and across a narrow neck of sand-hills in a westerly direction. Works comprise a dam 4,462 ft. long, with maximum bottom width 147 ft. and top width 13 ft., shutting off Lake Y from the Zuyder Zee. There are five large locks, six sluiceways, three swing-bridges (two railway and one roadway), and a harbour of 260 acres at the North Sea entrance, protected by two rubble stone breakwaters, 5,070 ft. long each, with pier on top formed of concrete blocks, 6 to 12 tons each. Canal is 16½ miles long, 88½ ft wide at bottom, 186 ft. at water level, and 23 ft. deep (now increased to 30 ft.). 21,000,000 cubic yards of soil and mud were excavated and dredged and 13,000 acres of land reclaimed. The sale of the latter realised about 70*l.* an acre, or a total of some 910,000*l.*, which mitigated the engineering cost. The largest type of dredger used could deposit 1,300 cubic yards of material on the banks in twelve hours, at 2*d.* per cubic yard. Permanent pumping machinery was installed for draining the adjacent lands into the canal and out again into the sea. Engineers, Sir John C. Hawkshaw and Mr. Dirke. Contractors for the whole of the works, Messrs. Henry Lea and Son. For full details see paper by Mr. Harrison Hayter read at the Institution of Civil Engineers in 1880, and printed in the *Proceedings*, vol. lxii. p. 1.

	Total.	Per Mile.
Constructional works only . . .	2,600,000*l.*	157,580*l.*
Other expenditure and charges . .	400,000*l.*	24,240*l.*
Whole cost	3,000,000*l.*	181,820*l.*

Caledonian Canal (1803–23).—From Inverness to Fort William, along the Great Glen of Scotland, and connects Inverness Firth with Loch Eil, having Lochs Ness (22 miles), Oich (6 miles), and Lochy (10 miles) in between. The summit level of 102 ft. is overcome by 28 locks, 14 on either side, each about 170 ft. long × 40 ft. wide; 23 miles of artificial or canal navigation in four stages, and 38 miles of natural lake navigation through the foregoing three lochs, the total distance between extremities being thus 61 miles. Canal is 50 ft. wide at bottom, 120 ft. at water level, and 17 to 20 ft. deep, for vessels up to 600 tons burden. Engineer, Thomas Telford. Total cost, including land, 1,311,270*l.*, or 57,010*l.* per mile of actual canal length of 23 miles.

Corinth Canal (1882–93).—Across the isthmus of Corinth, between Gulf of Corinth and Gulf of Aegina, in Greece, and mostly through solid rock with very deep cutting. The neck of land rises in the centre to 286 ft. above the bottom of the canal. Bottom width, 72 ft., and average depth, 26 ft. No locks. Length, 4 miles. Entrances at each end protected by solid jetties built out into the sea. Greek engineer, Matsos. Total cost, 1,400,000*l.*, or 350,000*l.* per mile.

Cronstadt and St. Petersburg Canal (1877–90).—Starts from the Neva and goes south-west for about 2 miles, when it curves and proceeds in a straight line to Cronstadt. Average width, 240 ft., and depth, 20 ft. No locks. Total length, 16 miles, including 10 miles bay channel and 5 miles canal proper. Costs per mile are based on the total length of 16 miles.

	Total.	Per Mile.
Constructional works only . . .	1,240,000*l.*	77,500*l.*
Other expenditure and charges . .	760,000*l.*	47,500*l.*
Whole cost	2,000,000*l.*	125,000*l.*

Elbe and Trave Canal (opened 1900).—In Germany. Width at bottom, 72 ft.; at top, 105 to 126 ft.; and depth, 10 ft. Length, 42 miles. 7 locks. Total cost, 1,177,700*l.*, or 28,040*l.* per mile.

Kiel Canal (1888–95).—Also known as the Kaiser Wilhelm Canal, or the Baltic and North Sea Canal, connecting Kiel in the Baltic to Elbe in the North Sea. Mostly through marshes or shallow lakes and river valleys, with tidal waterway throughout. Original dimensions: bottom width, 72–85 ft., surface width, 190–226 ft., and depth, 28–30 ft. (since increased to 150 ft., 335 ft.,

and 45 ft., respectively). Total excavation, 106,000,000 cubic yards. Two entrance locks, originally 492 ft. long × 82 ft. wide × 32 ft. deep over sill (now enlarged to 1,083 ft. × 148 ft. × 45 ft., and constructed in concrete, each lock having three pairs of caissons dividing the chambers into lengths of 725 ft. and 330 ft.). The original canal was completed in 1895, and the works for broadening and deepening in 1914. Breakwaters at each end. Length, 61 miles.

	Total.	Per Mile.
Original cost up to 1895, including land purchase	7,800,000*l.*	127,870*l.*
Enlargements and reconstructions up to 1914	11,200,000*l.*	183,605*l.*
Whole cost	19,000,000*l.*	311,475*l.*

Manchester Canal (1887–94).—Connects Manchester with Eastham, the Mersey port of Liverpool. Fifteen miles of canal proper, and 21 miles tidal waterway, or 36 miles total. Canal averages 120 ft. wide at bottom, 170 ft. at water level, and 26 ft. minimum depth (now increased to 28 ft.). Four sets of locks, with an average lift of 15 ft. each, thus raising the water level of the canal at Manchester to 60 ft. above mean sea-level at Liverpool. Capacity for 9,000 ton vessels, and it takes seven hours to pass through the whole distance and locks. The latter vary from 600 ft. × 80 ft. to 150 ft. × 30 ft., and sills 16–28 ft. deep below normal water-level of canal, the gates being moved by hydraulic machinery. The works include 160 acres of docks, with warehouses, machinery, and 95 miles of railway sidings, 6 high-level bridges, 7 swing-bridges, and the Barton swing aqueduct, 234 ft. long, for the Bridgewater Canal over the Irwell (to replace Brindley's fixed aqueduct), which latter canal had to be bought. 52,000,000 cubic yards of excavation and removal. Plant cost 980,000*l.*, and comprised engines, locomotives, steam pumps, cranes, piling machines, horses, wagons, temporary railway, etc. Principal engineer, Sir E. Leader Williams, assisted by W. Henry Hunter and others. Contractors, T. A. Walker (who died on November 25, 1889, during the progress of the work), and his executors, T. J. Reeves, L. P. Nott, and C. H. Walker, who continued. For full particulars see *History of the Manchester Ship Canal*, 2 vols., published by Sherratt & Hughes, 34 Cross Street, Manchester. Price 25*s.* Details of cost below are based on the total length of 36 miles :—

	Total.	Per Mile.
Purchase of Bridgewater Canal	1,783,000*l.*	111,438*l.*
Land and compensation	1,167,000*l.*	72,937*l.*
Constructing the canal and docks	9,000,000*l.*	562,500*l.*
Interest on capital during construction	1,050,000*l.*	65,625*l.*
Law charges, Parliamentary expenses, etc.	500,000*l.*	31,250*l.*
Whole cost	13,500,000*l.*	843,750*l.*
Average annual maintenance per mile of canal		2,000*l.*
Do. do. per acre of docks		400*l.*

Panama Canal (1904–15).—From Colon, on the Atlantic, to Panama on the Pacific. A concession was granted in 1876 to a French syndicate, which made surveys for two years and reported to an international congress at Paris in May, 1879. The Panama Canal Company was then floated, with Ferdinand de Lesseps as president, and preparatory work undertaken in 1881, the first excavation being made in January, 1882. The French scheme, however, was finally abandoned in 1904 owing to fever and bad administration, after the failure of both the first and a second company, and after only 12 miles had been cut out of the 54 originally proposed, and 50,000,000*l.* spent. On May 4, 1904, the United States Government bought the effects of the French company in Panama for 8,000,000*l.*, and started the American project as now completed. A strip of territory extending five miles on each side of the route of the canal was also purchased from Colombia for 2,000,000*l.* Colonel (now General) George W. Goethals, U.S.A. Engineers, was chairman of the Canal Commission which worked out the type and salient features.

Total length along axis, 50½ miles, but only 41½ miles within the coastlines. Rise of tide at Limon Bay in the Atlantic varies from 7 to 19 in., and from 8 to 21 ft. at Panama. The opening channel at sea-level, from Limon Bay to Gatun, is 7 miles long by 500 ft. wide and 41 ft. deep. At Gatun are three twin locks to raise vessels to the summit canal level, 85 ft. above sea, also an earthen dam, 8,000 ft. long, 1,500 to 2,000 ft. thick at the base, 100 ft. wide at top, and 115 ft. high, damming the Chagres River and forming the artificial Gatun Lake, 164 square miles area, with surface 85 ft. above sea-level, through which ships pass in a channel 500 to 1,000 ft. wide and 45 ft. deep. After 23½ miles of Gatun Lake the Gaillard Cut (formerly Culebra Cut) extends for 8 miles and 280 ft. maximum depth, with a channel 300 ft. wide and 45 ft. deep. Then a single twin lock, with 30 ft. drop, at Pedro Miguel to the small Miraflores Lake, where a channel, 1½ miles long by 500 ft. wide and 45 ft. deep, leads to Miraflores itself. Here two twin locks lower vessels, 31 ft. each lock, to the Pacific sea-level, and a channel 8 miles long, likewise 500 ft. wide and 45 ft. deep, conducts them to deep water in Panama Bay. In addition there are nearly 3 miles in locks and alongside approach walls. About 26 miles are artificial canal work, out of the total distance of 50½ miles.

Width of channel varies from 300 to 1,000 ft. at bottom, and depth 40 to 45 ft. The six pairs of locks are 1,000 ft. long × 110 ft. wide, with intermediate gates to divide them into two sections of 600 ft. and 400 ft., and 6 pairs of lock gates with steel frames and plates. There are 46 pairs of lock gates altogether, 46 to 82 ft. high, and the largest weighs 730 tons. Least depth of water over sills of locks when lake is at normal level is 41 ft.

The total excavation for the whole canal amounted to 220,000,000 cubic yards (130,000,000 in the dry, and 90,000,000 by dredges), of which about 112,000,000 yards was in the Culebra Cut, the most extensive excavation ever made. Concrete in the locks came to 4,500,000 cubic yards. Maximum number of employees at one time was 50,000 (6,000 Americans, 5,000 Europeans, and 39,000 negroes).

In addition to General Goethals, other engineers were Messrs. S. B. Williamson, chief of the Pacific Division, Gaillard, Sibert, Hodges, Goldwork, Schildhauer, Cornish, Zinn, Nichols, Alfred Noble, and others.

The canal was opened for traffic on August 15, 1914, the steamer passage being 10 hours each way. Ships are towed by electric cars or 'mules' running on rails alongside the waterway. Several landslides subsequently occurred necessitating temporary suspension of traffic till well into 1915.

Total cost was approximately as follows, the cost per mile being based on the total length of 50½ miles:—

	Total.	Per Mile.
Spent by the original French Canal Co. up to 1904 before abandonment . .	50,000,000*l.*	990,100*l.*
Purchase money paid to the French Canal Company	8,000,000*l.*	158,416*l.*
Sum paid to the Republic of Colombia or Panama for concession . . .	2,000,000*l.*	39,604*l.*
Constructional cost of American scheme, including terminal facilities . .	65,000,000*l.*	1,287,130*l.*
Whole cost	125,000,000*l.*	2,475,250*l.*

Saulte Ste. Marie Canal (opened 1895).—In Canada, connecting Lakes Superior and Huron, Known as the 'Soo,' and passes 20,000 vessels a year round the Saulte Ste. Marie Falls. Length, 1¼ miles. Width at bottom 142 ft., and depth 20 ft. It has the longest lock in the world, with gates operated by electric power. Total cost, 560,000*l.*, or 509,090*l.* per mile.

Suez Canal (1859–69).—Between Port Said on the Mediterranean and Suez on the Red Sea. M. Ferdinand de Lesseps, engineer and promoter. Total length all but 100 miles, including 60 miles through the shallow lakes of Menzaleh, Ballah, Timsah, and the Bitter Lakes, with and without dredging, and the rest actual canal formed by cutting. Sandy soil and a little rock. Sixty dredging machines were employed, and about 100,000,000 cubic yards of material excavated and dredged. Over 25,000 labourers were employed during the earlier period. Canal was originally 72 ft. wide at bottom, 196 to 328 ft. at water-level, and 16 ft. average depth (now increased to 147 ft., 420 ft., and 39 ft., respectively). No locks, as the canal is level throughout. Rise of tide is only about 1 ft. in the Mediterranean, and 6 ft. in the Red Sea. A slight current of 3 ft. per second keeps the canal clear. Passage takes 16 hours.

An auxiliary freshwater canal was constructed at the same time from the Nile, near Cairo, to Lake Timsah, and thence nearly parallel to the main canal as far as Suez, to supply fresh water and to convey provisions and materials, and afterwards to irrigate. It was 26 ft. wide at bottom, 56 ft. at surface, and 6½ ft. deep.

At Port Said the harbour encloses 450 acres, with an eastern breakwater 6,233 ft. long and a western breakwater 9,800 ft., composed of random concrete blocks weighing 20 tons. At Suez the outlet of the canal is protected on the south-west by a mole 2,900 ft. long, and on the north-west by a sold earthwork embankment.

Costs per mile are based on the total length of 100 miles.

	Total.	Per Mile.
Cost of promotion and preliminaries .	5,300,000*l.*	53,000*l.*
Constructional works only . . .	10,700,000*l.*	107,000*l.*
Enlargement, widening, and deepening since 1869.	4,000,000*l.*	40,000*l.*
Whole cost	20,000,000*l.*	200,000*l.*
Less indemnity granted in 1864 for loss of forced labour, about	4,000,000*l.*	40,000*l.*
Net cost	16,000,000*l.*	160,000*l.*

Welland Canal (opened 1833).—Constructed to avoid the break in communication between Lakes Erie and Ontario, Canada, caused by the falls in the Niagara River, and runs parallel to the latter on the west. Length, 26¾ miles. Twenty-seven locks, with total lift of 330 ft. Enlarged in 1867 to accommodate vessels of 400 tons. Again enlarged, 1874–87, to take vessels of 1,000 to 1,500 tons, so that the bottom width of canal would be 100 ft., and depth 14 ft. Locks increased to 270 ft. long by 45 ft. wide, and 14 ft. depth of water on the sills.

	Total.	Per Mile.
Cost of original canal opened in 1833	2,700,000*l.*	100,935*l.*
Cost of enlargement from 1874–87	2,300,000*l.*	86,019*l.*
Whole cost	5,000,000*l.*	186,954*l.*

Concrete.

(*London Prices, July*, 1929.)

The following prices are based on best British Portland cement at 55*s.* per ton to contractor delivered on site, including use of bags and returning empties. Clean pit sand 12*s.* per yard cube, Thames ballast 10*s.*, gravel 12*s.*, and 1½ in. broken stone 14*s.*, ditto. Wages, labourer, 1*s.* 4*d.* per hour.

The rates for measured work include materials, measuring and mixing by hand, wheeling up to 20 yds., laying and ramming, and 17 per cent. establishment charges and profit. Machine-mixed concrete would be about 3*s.* to 6*s.* per cubic yard cheaper.

Plain Concrete.

		s.	*d.*
Portland cement concrete, 1 to 6, with unscreened Thames ballast in foundations, walls, and masses exceeding 12 ins. thick	per yd. cube	36	0
Ditto, 1 : 3 : 6, with 1 cement, 3 sand, and 6 clean pit gravel, ditto	,,	37	0
Ditto, 1 : 3 : 6, with 1 cement, 3 sand, and 6 local broken stone, 1½ in. gauge graded down to ¼ in., in foundations, walls, and masses	,,	40	0
Add if in foundations and walls not exceeding 12 ins. thick	,,	2	0
Add if in underpinning in short lengths up to 5 ft.	,,	6	0
Add if executed between high and low water mark, including covering with canvas to protect against tides	,,	8	0
Deduct from the foregoing 1 : 3 : 6 proportions if the proportion is 1 : 4 : 8	,,	3	0
Portland cement concrete, 1 : 3 : 6, with 1 cement, 3 sand, and 6 clean pit gravel, spade finish. spread and levelled in beds, pavings, or ground floors, 6 ins. thick	per yd. sup.	6	0
Add for floated or trowelled surface with 1 cement and 2 sand, ¾ in. thick, as a screed or bed	,,	1	9
Granitic surface layer of 1 cement to 2 granite chippings, 1 in. thick, floated and trowelled to a smooth face whilst concrete is unset	,,	4	0
Hard dry filling under concrete, of clean broken brick, hard core, mason's spalls, etc., spread and levelled 6 ins. thick	,,	2	6
Portland cement concrete, 1 : 2 : 4, with clean pit gravel, ballast, or crushed aggregate, graded ¾ in. to ¼ in. gauge, cast *in situ* complete, with exposed faces left clean and perfect, including use of casings, for kerbs and channels to footpaths, roads, pavements, etc.	per ft. cube	2	4
Ditto pre-cast solid building blocks, exceeding 4 ins. thick, and set in 1 to 3 cement mortar	,,	2	10
Ditto pre-cast hollow blocks (measured as solid), ditto, ditto	,,	2	6
Ditto pre-cast lintels, door and window heads, window sills, steps, copings, cornices, quoins, and setting and jointing in 1 to 3 cement mortar	,,	4	9

Reinforced Concrete.

Reinforcement varies from ½ to 5 per cent. sectional area of the steel compared with the sectional area of the concrete, according to position.

1 per cent. volume of steel = 132 lbs. reinforcement per yard cube of concrete.

General economy of reinforced concrete construction for large structures, and over steel-framed buildings of equal strength, is 10–20 per cent., and over brick buildings and in heavy foundations 20–30 per cent.

Reinforced concrete factories, offices, stores, warehouses, etc., cost 10*d.* to 1*s.* 2*d.* per ft. cube.

Proportionate costs vary : ⅛ concrete, ⅛ steel, ⅛ formwork, to ½, ¼, ¼, respectively.

General proportions—1 : 1½ : 3 and 1 : 2 : 4. Cement should equal British Standard Specification (B.S.S. No. 12). Ferrocrete, Super-Cement, and Ciment Fondu harden much more quickly and are stronger, but more expensive.

Sand graded $\frac{3}{16}$ in. to $\frac{1}{10}$ in. (75 per cent. to pass $\frac{1}{8}$ in.), and aggregate $\frac{3}{4}$ in. to $\frac{3}{16}$ in. Concrete to be quickly deposited in layers not exceeding 6 ins. thick and 3 ins. next reinforcing bars, and in quantities not more than 2 ft. cube, closely punned round the steel.

Each class of work and story to be given separately, and heights stated. The space occupied by the steel is not to be deducted. Prices for mass concrete include forming chamfers, splays, rounded angles, etc., but the use of moulds for these should be taken under formwork.

The concrete, the steel, and the formwork are first priced separately, then combined into a condensed table of complete work.

Concrete Piles—

		s.	d.
Pre-cast reinforced Portland cement concrete, 1 : 1½ : 3, with 1 cement, 1½ washed sand, and 3 local broken stone, ¾ in. or ⅜ in. gauge graded down to $\frac{3}{16}$ in., in bearing or sheet piles, including all moulds, and planted in position ready for driving (exclusive of steel reinforcement and pile shoes)	per ft. cube	5	0
Steel reinforcement and shoes for ditto, and fixing	,,	4	0
Placing and driving ditto not less than 144 sq. ins. section, including all working apparatus, such as pile engine, etc., in ordinary ground (portion in soil only to be measured)	,,	4	0
Ditto ditto ditto in tide work	,,	5	6
Ditto ditto if driven from barges or floating stages, including use of same, extra over tide work	,,	1	6
Simplex reinforced concrete piles, 16 ins. diameter, cast in place and driven complete (8 or 10 piles, of 25 ft. average length and reinforcement provided, can be driven per 8-hr. day)	per ft. run	12	0
Allowance for bringing, erecting, and removing pile engine and tackle for driving, etc.	per job	15*l.*	to 25*l.*

Concrete Foundations, Walls, etc.—

		s.	d.
Reinforced Portland cement concrete (only), 1 : 2 : 4, with 1 cement, 2 washed sand, and 4 local broken stone, ¾ in. gauge graded down to $\frac{3}{16}$ in., in foundations and masses	per yd. cube	50	0
Ditto in walls exceeding 12 ins. total thickness	,,	54	0
Ditto beams, not exceeding 72 ins. sectional area, to floors or roofs	per ft. cube	2	2
Ditto large beams, exceeding 72 ins. but not exceeding 144 ins., ditto	,,	2	0
Ditto independent piers, columns, struts, or pilasters	,,	2	4
Ditto steps, stairs, winders, strings, carriages, etc., any section	,,	2	8
Ditto floor slabs or flat roofs, 4 ins. thick, and hoisting 30 ft.	per yd. sup.	6	4
Ditto ditto ditto 6 ins. thick, ditto	,,	9	6
Ditto walls, 6 ins. thick, measured between piers or projections	,,	10	0

Steel Reinforcement—

		s.	d.
Mild high-tension steel in accordance with B.S.S. No. 15, British Standard Specification for Structural Steel, Class A, in plain reinforcement (round, square, or flat bars), including cutting, bending, hoisting, 30 ft., assembling or putting into position, stout binding wire, and fixing complete in foundations, walls, columns, floors, etc., in			
¾ in. to 1½ in. bars	per cwt.	21	6
½ in. to ⅝ in. ,,	,,	22	6
¼ in. to ⅜ in. ,,	,,	23	0
Steel in proprietory systems of trussed or stirrup bars, and fixed	,,	26	0
Ditto ditto indented, twisted, or studded bars, ditto	,,	30	0
Fixing only sheet reinforcement, such as expanded metal, fabric, and mesh systems, 4–16 lbs. per yd. sup., including cutting, bending, or wiring (measured net, with no allowance for laps)	per yd. sup.	0	6

Formwork—

		s.	d.
Use and waste of 1½ in. simple flat centering, machine-planed one side, edges shot, to flat concrete floors and roofs, including about 14 ft. cube rough timber supports, ties and braces, and wedges, cleats, clamps, dog-irons, straps, etc., erection, cutting, maintenance, striking, and removal, average 12 ft. high	per square	52	0
Ditto ditto if to curved ceilings or roofs	,,	62	0

		s.	d.
Use and waste of 1 in. to 1½ in. strong shuttering to concrete walls, vertical or battering, including all supports, struts, etc., erection, cutting, maintenance, and removal (both sides measured)	per square	45	0
Ditto ditto if curved	,,	55	0
Add if boarding is machine-planed one side, thicknessed, and edges shot	,,	5	0
Limewashing internal surfaces of formwork, or treating with soft soap or mould oil, to prevent the concrete adhering	per yd. sup.	0	3
Use and waste of fir in rough timber supports, shoring, etc.	per ft. cube	3	0
Use and waste of casing, planed one side and edges shot, to concrete beams, average 12 ins. × 6 ins., including sides and soffits	per ft. sup.	1	0
Ditto to concrete pillars or columns, square, including supports	,,	0	10
Ditto ditto ditto circular, ditto	,,	1	3
Use and waste of casing in narrow widths, under 12 ins., to openings in concrete walls, floors, roofs, etc	per ft. run	0	6
Extra for fillets to internal angles of casing or shuttering to form chamfers, splays, rebates, rounded angles, etc., not exceeding 9 ins. girth	,,	0	3
Labour forming small splays, grooves, rounded edges, etc., not exceeding 2 ins. girth	,,	0	2
Raking, cutting, and waste to shuttering, not exceeding 1½ ins. thick	,,	0	3

Complete Work.—The following may give a general idea of the whole cost, including concrete, steel reinforcement, and formwork, but there are so many systems that it is impossible to be more definite, and the range of values must be great :—

			s.	s.
Reinforced concrete	12 ins. × 12 ins. piles, including driving, etc., complete	per ft. run	12 to	18
,, ,,	12 ins. pillars or columns, square or circular	,,	6 ,,	12
,, ,,	steps, stairs, and sills, average 12 ins. × 6 ins.	,,	4 ,,	8
,, ,,	floors, 4 ins. to 6 ins. thick, including beams	per yd. sup.	20 ,,	30
,, ,,	flat roofs, 4 ins. to 6 ins. thick, including beams	,,	20 ,,	30
,, ,,	walls, 4 ins. to 6 ins. thick, vertical or battering	,,	12 ,,	24
,, ,,	partitions, 2 ins. to 4 ins. thick, smooth on both sides	,,	10 ,,	16
,, ,,	foundations, thick walls, and masses	per yd. cube	70 ,,	100

Reinforced Granite Concrete Tubes.

Manufactured by John Ellis & Sons, Ltd., 16 Pocklington's Walk, Leicester, of best Portland cement and Mountsorrel granite, 1 to 3, crushed, washed, and passed through ¼-in. mesh, and with sufficient sand to fill up all interstices. The tubes are made both with and without steel ribs, the latter being ¼ in. welded steel rings placed in the centre of the material, 12 ins. apart. The concrete is cast in vertical steel moulds, filled in thin layers, and rammed with a heavy machine-driven hammer. The pipes are left in the moulds for three days, after which they are put in the open air to mature for six months.

Prices of reinforced circular sewer tubes free on rail at works, Barrow-on-Soar, L.M.S. Railway (July, 1928) :—

Internal Diameter.	Thickness in inches.	Stock Lengths.	Weight per ft. run.	Feet per ton.	Price of Tube per ft. run.
ins.	ins.	ft.	lbs.	ft.	s. d.
12	1¼	3	56	40	2 6
15	1½	2 and 3	86	26	3 0
18	1⅝	2 ,, 3	97	23	3 6
21	1⅝	2½ ,, 3	132	17	4 6
24	2	2 ,, 3	176	12¾	6 0
27	2	2 ,, 3	199	11¼	7 0
27	2¼	2 ,, 3	219	10¼	8 0
30	2½	2 ,, 3	276	8⅛	9 3
33	2½	3	289	7⅞	10 0
36	2½	3	326	6¾	11 0
36	2⅝	2 and 3	345	6½	12 0
39	3	3	415	5⅝	14 0
42	3	2 and	472	4¾	16 0
45	3¼	3	541	4½	18 0
48	3½	2 and 3	640	3¾	20 0
57	4½	3	943	2⅝	31 6
60	5	3	1120	2	37 6

Laying.—Cost of laying and jointing in addition. The tubes are usually laid on a square concrete bed raised half-way up the outside, and 6 ins. thick. The ogee joints are sealed with cement mortar, 1 to 1.

Connections.—Bends, junctions, circular manholes, well tubes, etc., are also supplied of granite concrete.

Other Tubes.—Socket and spigot sewer tubes, 15 ins. to 24 ins. diameter, and egg-shaped tubes, with internal measurements 18 ins. × 12 ins. to 60 ins. × 40 ins., are similarly made.

Stanton-Hume Reinforced Concrete Pipes.

The Stanton-Hume Reinforced Concrete Pipe is manufactured by the Stanton Ironworks Co., Ltd., near Nottingham, under sole licence from the Hume Pipe and Concrete Construction Co., Ltd., London. A hard, dense pipe is produced, owing to the centrifugal action of the moulding machinery, and the concrete mixture spreads itself evenly over the inner surface, while the circular motion expels excess air and water, so that there are no voids. All materials are mechanically tested in laboratories, then carefully graded and mixed by special apparatus, and the sand automatically washed. The pipe is particularly suitable for drainage and sewage work, as it is very strong, the interna. surface is abnormally smooth, owing to the longer lengths fewer joints are required, and cost is low. The reinforcement is a spirally wound steel wire cage of great tensile strength, kept in a central position by centrifugal tendency.

The pipes are made 4 ins. to 60 ins. diameter, and in classes A, B, C, D, E, for working pressures of 10, 25, 50, 75, 100 lbs. per sq. in. respectively. Proportions, 1 : 2 and 1 : 3 graded granite, finely crushed.

Prices delivered 50 miles from Stanton Gate at Ilkeston, near Nottingham (July, 1928) :—

Internal Diameter.	Thickness in inches.	External Diameter.	Stock Lengths.	Weight of Pipe for Class A.	Weight of Collar A.	Price of Pipe per ft. run.
ins.	ins.	ins.	ft.	lbs.	lbs.	*s.* *d.*
4	1	6	6	104	13½	0 9
6	1	8	6	146	17	1 1
9	1⅛	11¼	6	237	26	1 9
12	1⅜	14¾	6	380	40	2 9
15	1½	18	6	513	56	3 8
18	1⅝	21¼	8	887	75	4 8
21	1⅞	24½	8	1,111	92	5 9
24	1⅞	27¾	8	1,350	118	7 6
27	2	31	8	1,612	132	8 9
30	2⅛	34¼	8	1,906	175	10 6
33	2¼	37½	8	2,220	202	12 3
36	2⅜	40¾	8	2,540	240	15 0
42	2½	47	8	3,110	302	20 0
48	2¾	53½	8	3,900	415	25 0
54	3	60	8	4,790	560	32 6
60	3	66	8	5,310	620	38 6

Joints.—The above prices include one collar for each length of pipe. Pipes with ogee joints 5 per cent. less. Jointing requires skilled labour, but experienced men can be sent ; 1 cement to 2 sand.

Laying.— Cost of laying and jointing extra to rates in table. Reinforced bends, tees, angle branches, etc., are also made.

Deep-water Quays.

The structural conditions of deep-water quays are so variable that the assumption of a unit of cost is misleading. For ocean-going shipping in the Thames, however, the rates between 1919–22 (post-war) varied from 50*l.* to 200*l.* per ft. run.

Deep-water Quay, Greenhithe (1919–21).—On the south bank of the river Thames, and was an extension of the existing wharves of the Empire Paper Mills. Tidal range over 18 ft., with 17 ft. depth at low-water ordinary spring tides. Length of new section of the approach 455 ft., with minimum width of 8 ft., and new deep-water berthage at end 303 ft. by 52 ft. width throughout, and three splays at corners. Total deck area of new works approximately 24,600 sq. ft. Quay carried out in creosoted Oregon and pitch pine, with steel superstructure. Engineers, Messrs. Carey and Latham.

Total cost, 70,783*l.*, or 2*l.* 17*s.* 7*d.* per ft. sup. of new wharf accommodation obtained. About 93*l.* per ft. run, including approaches.

Deep-water Quay, Shellhaven (1920–21).—On the Essex side of the river Thames, and consisted of the extension of a deep-water berthage for an oil storage depot. Tidal range 18 ft., with 29 ft. depth at low-water ordinary spring tides. Length of new quay approach 560 ft. by 18 ft. wide, and new deep-water berthage at end 420 ft. long by 40 ft. deck width, the two forming a **T** shape. Total deck area approximately 31,000 sq. ft. All of reinforced concrete on the Coignet system. Engineers, Messrs. Carey and Latham, and contractors Messrs. Mowlem & Co.

Total cost 80,000*l.*, or 2*l.* 11*s.* 7*d.* per ft. sup. of new wharf accommodation obtained. About 82*l.* per ft. run, including approaches.

Docks.

(*Estimated Costs*, 1930.)

Wet docks, including wharves, gates, locks, machinery, etc., but excluding cost of land :— 50,000*l.* to 100,000*l.* per acre of water area.

Dry or graving docks for repairs, including equipment and pumping machinery :— 4*l.* to 8*l.* per yard cube of internal capacity.

Steel floating docks for repairs, in terms of lifting power 15*l.* to 25*l.* per ton.

Dock gates of greenheart, 70 to 90 ft. wide and 40 to 50 ft. high, including hydraulic machinery . . . 4*l.* to 5*l.* per ft. sup.

Ditto of steel, ditto, ditto . . . . . 3*l.* to 5*l.* ,,

Caissons, traversing or floating, 60 to 90 ft. wide, and 30 to 40 ft. high, including hydraulic machinery . 5*l.* to 10*l.* per ft. sup. of waterway.

Dock walls, of concrete, stone or granite, with concrete backing, including digging . . . . . 40*s.* to 90*s.* per yd. cube.

Actual Costs of wet docks, including dock walls, gates, locks, etc., per acre of water area :—

	£
Avonmouth Docks, near Bristol (1868–77)	22,600
Barry Docks, near Cardiff (1889). Water area, 114 acres. Total cost, 3,072,000*l.*	26,947
Cardiff. Water area, 50 acres. Total cost, 1,500,000*l.*	30,000
,, Bute Dock Extension. Water area, 35 acres	22,000
,, West Bute Dock (1839). Water area, 22 acres. Total cost, 400,000*l.*	18,180
,, Roath Dock (1887). Water area, 33 acres. Total cost, 500,000*l.* .	15,150
Glasgow, Queen's Dock	24,500
Hull, Alexandra Dock	28,900
Immingham, near Grimsby (1912). Water area, 56 acres. Total cost, including land, railway sidings, dock sheds, coal hoists, etc., 2,600,000*l.* . . .	46,430
Liverpool, Alexandra Dock	23,300
,, North Extension. Water area, 83 acres. Total cost, 2,640,000*l.* .	31,810
London, King George V Dock (opened 1921). Concrete walls, 7 reinforced concrete jetties, entrance lock, &c. Water area, 64 acres. Total cost, with equipment, 4,130,000*l.*	64,531
London, St. Katherine's Docks	36,000
Newport, S. Alexandra Docks (1893). Water area, 20 acres. Total cost, 500,000*l.*	25,000
Swansea, Prince of Wales' Docks (1879). Water area, 28 acres . . .	18,600

Gladstone Docks, Liverpool (1910–27).—The whole scheme embraces :—a new River or Entrance Lock (1,070 ft. long and 130 ft. wide, 22 ft. depth on the sills at low water ordinary spring tides, and 48 ft. at high-water ditto, allowing the largest ship to enter or leave on every single tide of the year); a Connecting Lock (645 ft. long and 90 ft. wide, between the existing dock system and the new docks); a Turning Dock, called the 'Gladstone Dock' (1,594 ft. long and 942 ft. extreme width, water area 25 acres, with a shed on the north quay, 925 ft. × 100 ft. and a shed on the west quay, 526 ft. × 100 ft.); a Branch Dock, called the 'Gladstone Dock No. 1' (1,420 ft. long and 400 ft. wide, opening out of the turning dock, with north shed 1,252 ft. × 100 ft., and south shed, 1,502 ft. × 150 ft., both of reinforced concrete, flat roofs and three storey); another Branch Dock, called the 'Gladstone Dock, No. 2' (1,285 ft. long and 400 ft. wide, also opening out of the turning dock, with north and south sheds, 1,202 ft. × 100 ft. and 1,277 ft. × 100 ft., of reinforced concrete as before); and the 'Gladstone Graving

Dock,' 1910–13 (1,050 ft. long and 141 ft. wide at bottom and 155 ft. at top, 43 ft. depth on sill at ordinary spring tides, being the largest dry dock in Europe, and can also be used as a wet dock, with a single-storey shed the full length of the north quay); also large crane and jigger equipment at sheds, tracks, rail facilities, electric power, engines, pumps, etc.

Engineers, Mr. T. M. Newell, M.I.C.E., engineer-in-chief of the Mersey Docks and Harbour Board, and Mr. J. A. Newell, A.M.I.C.E., and Mr. G. E. C. Callow, A.M.I.C.E., resident engineers. The work was carried out by direct labour, but the lock gates were made by Sir W. G. Armstrong Whitworth & Co., cranes by Messrs. Stothert and Pitt, Ltd.,of Bath, and details by other firms.

The whole extensions comprise—58¼ acres of water area, 3 miles of quayage, 19 acres of ground covered by sheds, and 60½ acres gross floor area of sheds. Total cost over 7,500,000*l.*, or 128,755*l.* per water acre.

Actual Costs of dry or graving docks for repairs, including equipment :—

	Per yard cube of internal capacity. £	*s.*	*d.*
Aberdeen. Internal size, 524 ft. × 73 ft. at surface level. Total 46,000*l.*	1	15	0
Belfast (1905–12). Length over all, 901 ft. Total cost, 350,000*l.*	2	1	0
Glasgow. Internal capacity, 81,555 yds. cube. Stone and concrete	2	9	0
Hartlepool. Brick and concrete, 570 ft. × 75 ft. × 17 ft. deep	1	8	0
Liverpool. Gladstone Dock (1910–13). Total cost, 500,000*l.*	1	13	0
Otago, New Zealand. Internal capacity, 37,000 yds. cube. Total 75,000*l.*	2	0	0
Portsmouth. Granite with brick and concrete backing; 42 ft. deep	2	0	0

Drainage.

4-in. and 6-in. stoneware drains, jointed in cement, including trenches 3 ft. deep and concrete bed, 6 ins. thick . . . . . 2*s.* to 3*s.* per ft. run

Ditto ditto with manholes, ventilating pipes, etc. . . 5*s.* to 6*s.* per ft. run.

Manholes and inspection chambers, 3 ft. × 2 ft. 6 ins. × 3 ft. 6 ins. deep, complete, including digging, concrete, brick sides, iron cover, etc. . 8*l.* to 10*l.* each.

Add extra for every additional foot in depth . . . . . 16*s.* to 18*s.* per ft. deep.

Drains and sewers for estate development and town planning schemes . 200*l.* to 400*l.* per acre.

Drainage and sewage disposal works for cities and towns . . . 3*l.* to 6*l.* per inhabitant, 20*l.* to 30*l.* per house.

Reconstruction of Drainage, Stanhope Lines, Aldershot (1893).—Combined water carriage system with 4 in., 6 in., 9 in., and 12 in. glazed stoneware pipes (total, 54,670 yds. run), 2 to 6 ft. deep, 500 Jennings' latrines, 500 urinal stalls, 80 w.c.'s, with 3 gal. flushing cisterns, 200 gal. galvanised iron automatic cisterns, and 16 100-gal. brick automatic flushing tanks, with disposal of sewage by irrigation on War Department land. Occupation of barracks, 8,000 adults, 200 children, and 200 horses. Total cost, exclusive of sewage disposal works, 20,500*l.*, or 2*l.* 10*s.* per head of occupation exclusive of horses; 7*s.* 6*d.* per yd. run of excavation.

Drainage of Land.

Agricultural, or subsoil, unglazed earthenware drain pipes laid dry in 12 in. or 15 in. lengths, without jointing material and ends simply abutting. Depths and distances apart vary according to nature of soil. Cost includes digging, filling, pipes, and laying.

	Cost per acre.
In compact or heavy soils, drains 5 to 8 yds. apart, and 2 ft. 6 ins. to 3 ft. deep	6*l.* to 10*l.*
In medium soils, drains 9 to 10 yds. apart, and 3 ft. to 3 ft. 6 ins. deep	5*l.* to 6*l.*
In porous or light soils, drains 11 to 22 yds. apart, and 3 ft. 6 ins. to 4 ft. 6 ins. deep	4*l.* to 5*l.*

Dredging.

Dredging Plant.—Modern dredging appliances are of two main classes, with subdivisions and pre-war costs as follows :—

Class I.—Digging dredgers, comprising :

(*a*) Bucket dredger, or ladder (single or double), or elevator dredger, with a continuous band of buckets.

	£
With 5 ft. cube bucket, single ladder, raising 40 ft.	7,000
,, 15 ,, ,, ,, 45 ,,	27,000
,, 27 ,, ,, ,, ,, 55 ,,	43,000

(*b*) Dipper dredger, with a single bucket at the extremity of a long arm or lever. Almost purely an American type.
With 1 to 2 yds. cube dipper, hull of timber, 1,600*l.* to 2,400*l.*
With 3½ to 4 yds. cube dipper, dredging to depth of 35 ft., 16,000*l.* to 18,000*l.*
With 10 yds. cube dipper, dredging to depth of 35 ft., 26,000*l.* to 28,000*l.*

(*c*) Grab or grapple dredger, with a drop bucket suspended at the end of a chain.
A twin-screw hopper dredger, with hopper capacity of 12,000 tons, fitted with five hydraulic grab cranes each of 5 tons bucket capacity, working to a depth of 47 ft., has cost 35,000*l.*

(*d*) Hand or bag and spoon dredger, which consists of a bag attached to a steel rim at the end of a long pole, and is suitable only for mud in ponds and canals.

Class II.—Suction or hydraulic dredgers, comprising:

(*a*) Sand pump dredger, with centrifugal pump.
A 2,000-ton suction hopper dredger would cost 50,000*l.*

(*b*) Suction cutter dredger, with water jets and rotary cutters.
A suction hopper dredger with hopper capacity of 70,000 cub. ft., capable of raising 4,000 tons of sand per hour from a depth of 70 ft., has cost 75,000*l.*

(*c*) Compound dredger, fitted with both the suction or suction cutter and a bucket ladder.
A sea-going hopper dredger, fitted with both ladder buckets (18 cub. ft.) and suction pumps, capable of dredging 400 to 650 yds. cube per hour from a depth of 50 ft., has cost 53,000*l.*
Rock cutters are not dredgers, but an auxiliary class.

Cost of Work.—Costs include use of plant, dredging, and removing and depositing excavated material at sea. Steam dredgers cost 10,000*l.* to 70,000*l.* each; steam hopper barges in attendance, of 800 tons or 800 yds. cube capacity, with a speed of 11 knots per hour, cost 18,000*l.* to 20,000*l.*; ordinary hopper and dredger barges, 300*l.* to 1,000*l.* Pre-war.

Description.	Material.	Per yd. cube.	Per ton.
Bucket dredging, or ladder dredging	Mud, sand, or soft clay	1*s.* to 2*s.*	9*d.* to 1*s.*
	Gravel or stiff clay	2*s.* ,, 4*s.*	1*s.* ,, 2*s.*
Grab dredging, or grapple dredging	Mud, sand, or soft clay	2*s.* ,, 4*s.*	1*s.* ,, 2*s.*
	Gravel or stiff clay	3*s.* ,, 5*s.*	2*s.* ,, 3*s.*
Hand dredging, or 'bag and spoon dredging'	Mud, sand, or soft clay	3*s.* ,, 4*s.*	2*s.* ,, 3*s.*
	Gravel or stiff clay	4*s.* ,, 6*s.*	3*s.* ,, 4*s.*
Pump dredging, 'suction or hydraulic dredging'	Mud, sand, or peat	6*d.* ,, 1*s.*	4*d.* ,, 9*d.*

Grab dredging can be done for as little as 2*d.* to 6*d.* per yd. cube, and sand pump dredging for 1*d.* ditto, but a great deal depends on the kind of spoil and distance to be carried.

Alluvial Mining.—Dredging for alluvial mining costs anything from 1*d.* to 1*s.* per yd. cube (pre-war), depending upon character of ground, depth, quantity treated, climate, transport, power, labour, management, types of dredges capacity of buckets, operating time, etc.

Mersey.—At the bar and in the entrance channels of the Mersey nearly fifteen million cubic yards of sand were removed annually at a pre-war cost of 6*d.* per yd. cube, exclusive of interest and depreciation on the plant.

Mississippi River (1907).—Three pipe-line suction-cutter dredges got up 1,279,000 cu. yds. including cost of idle time, for 4½*d.* per yd. cube. In 1908 the same dredges lifted 989,000 cu. yds., ditto, for 5½*d.* per yd. cube.

Newry.—After blasting the bottom in a depth of 6 to 8 ft. at low water, the material was removed by dredging at 4*s.* to 5*s.* per yd. cube.

New York Harbour (1909).—Four sea-going suction dredgers removed 10,786,638 cu. yds., including dredging, surveys, contingencies, and supervision, for 2*d.* per yd. cube. Another dredger disposed of 1,675,562 cu. yds. at 2½*d.* per yd. cube.

Panama Canal (1910).—Costs of removal of various quantities by different kinds of dredgers worked out at:

Removal of	6,083,902	cu. yds. by	two sea-going suction dredgers	3¾*d.* per yd. cube
,,	1,372,665	,, ,,	one ladder dredger	8*d.* ,,
,,	560,622	,, ,,	,, ,,	1*s.* 1¾*d.* ,,
,,	1,013,485	,, ,,	two small dipper dredgers	2*s.* 4*d.* ,,
,,	2,472,822	,, ,,	two 20-in. pipe-line suction dredgers	1*s.* 2*d.* ,,
,,	5,800,000	,, ,,	two dipper dredgers	2½*d.* to 5½*d.* ,,

Port Natal, Durban (1903–14).—Cost of pump dredging in sea, including all charges for working, maintenance, insurance, depreciation, and interest on capital, with coal at only 8*s.* per ton, 2½*d.* to 7*d.* per ton of material handled.

Severn.—Blasting and dredging the marl beds, 4*s.* per yd. cube.

Siam (1920).—Dredging heavy clay from irrigation canal in Siam, 85 ft. wide by 8 ft. deep, by a Lobnitz dipper dredge with buckets of 2½ yds. cube capacity, working at a speed of 30 to 40 seconds per dip. Total quantity raised was 312,130 cu. yds. in one place, running 9 hours per day, or an average of 26,010 cu. yds. per month. Average cost for year was 3*d.* per yd. cube, including labour, oil fuel, supplies, repairs, and every expense except interest and depreciation. Repairs, 4·3 per cent. of total cost.

Tees.—Blasting and dredging. In 1875 holes were drilled in the bed of the river Tees 7 to 9 ft. deep and 10 ft. apart, from a dredger; then dynamite blasting in 2 lb. charges. Average depth of rock blasted 4 ft. 6 in., oolite shale. 110,000 yds. cube were blasted at 3*s.* 1*d.* per yd. cube, so as to be lifted by the dredger.

Ladder dredging in the Tees, mostly in hard boulder clay, and lifting stones and tree trunks, cost 1*s.* 6¾*d.* per yd. cube.

Thames.—Contract cost of lifting ballast and clay, by ladder or bucket dredgers from the Thames below London Bridge has varied from 1*s.* 4*d.* to 2*s.* 6*d.* per yd. cube, depending on distance material had to be conveyed.

Rock-cutting and Dredging.

Rock-cutting Plant.—The sub-aqueous Lobnitz Patent Rock-breaker or Rock-cutter, made by Lobnitz & Co., Ltd., shipbuilders and engineers, Renfrew, Scotland, is usually employed. The rock-breaker chisel, or rock-cutter itself, consists of a compressed steel cone-shaped point fitted to a solid steel shaft, 15 to 18 in. diameter and 40 to 50 ft. long, depending on depth of water, and weighing from 6 to 25 tons. This drops 6 to 10 ft. on the same place, from a frame mounted on a barge fitted with steam winch, hoisting gear, steel wire ropes, mooring chains, etc. No explosives are used. The striking points are marked on a chart, and the holes are spaced about a yard apart. After a penetration of 3 ft. on one spot the rock is cut, and then dredged away in horizontal layers. The general result is 2 cu. ft. of rock broken per blow, suitable for bucket dredging afterwards to remove the pulverised stone. And 2 cu. ft. × 150 blows per hour on an average = 300 cu. ft. ÷ 27 = 11 yds. cube per hour for a single-cutter machine, or say 100 yds. cube per working day of 9 hours. Output of a double-cutter machine is about one-half more. A crew of four men is required on a barge with one cutter, and six men with two cutters, the barge being shifted after a hole has been made to the next position. Skilled labour is unnecessary. 1 ton of coal is consumed per working day by a single 10-ton cutter, and 1½ tons by a double 10-ton cutter. The cost of oil, stores, and repairs does not exceed the outlay for coal and wages.

Blyth Harbour, Northumberland (1906).—Rock-cutting in friable to very hard sandstone by the Lobnitz Rock-breaker steel ram weighing 15 tons, falling 8 ft. to a depth of 3 ft. in the rock in 8 or 9 blows, to allow of being dredged to a depth of 2 ft. 6 ins. Average quantity was 908 cu. yds. of rock broken by one machine per week, night and day, allowing for all stoppages, and based on six months' working. Details per week for 908 cu. yds. was:

	£	*s.*	*d.*
Wages for men on dredger	16	1	6
Coal, stores, and water	6	10	7
Estimated cost of repairs, renewals of rams, ropes, etc.	22	0	0
Insurance at 30*s.* per cent. = 120*l.* per annum	1	19	2
908)	46	11	3
Rate per yard cube	0	1	0¼
Add 4 per cent. interest on cost of one Rock-breaker at 6,800*l.*, and 2½ per cent. for depreciation, making a further	0	0	2¼
Total cost per yard cube	0	1	2½

As compared with blasting, the rock-cutting disintegrates and breaks the rock into smaller pieces, so that the quantity lifted by the dredgers in a given time is about 15 per cent. more than that of blasted rock. The comparative cost of removal under the two systems of blasting and rock-cutting is as follows:—

	s.	*d.*
Blasting:—		
Drilling and blasting rock in position	3	0
Dredging and removing débris, 2*s.* 6*d.*+ 8*d.* for interest and depreciation on the dredger	3	2
Cost per yard cube	6	2
Rock-cutting:—		
Cutting rock by rock-breaker as already detailed	1	2½
Dredging and removing débris, 2*s.* 2*d.*+ 7*d.* for interest and depreciation on the dredger	2	9
Cost per yard cube	3	11½

Difference in cost per yard cube in favour of the removal of rock by means of the rock-breaker was thus 6*s.* 2*d.* *less* 3*s.* 11½*d.*= 2*s.* 2½*d.* Saving on 500,000 cu. yds. executed was accordingly 55,200*l.*, after the drilling and blasting had been tried and abandoned.

Manchester (1905–6).—Deepening a length of 14 miles of the Manchester Ship Canal from 26 ft. to 28 ft. by a Lobnitz Rock-cutter No. 1, designed to work in sandstone of varying degrees of hardness, the average quantity broken per month (over a period of 10 months) being 6,403 cu. yds. at an average cost of 9*d.* per yd. cube.

The cost of rock-breaking and dredging on the same canal in April 1907, by the Lobnitz dredger was as below. The price of one Rock-cutter was 6,800*l.*, and if 4 per cent. is allowed for interest, and 2½ per cent. for depreciation, the additional cost per yard cube is 2¼d., as added. 17,060 cu. yds. were broken, the rock being sandstone of different hardness, with some stiff marl.

	s.	*d.*
Breaking, excluding cost of plant, but including maintenance and repairs	0	5½
Dredging the broken rock	0	5½
Barging and tipping	0	6¾
Towage	0	2¼
	1	8¼
Add interest and depreciation on cost of plant	0	2¼
Total cost per yard cube	1	10½

Suez Canal.—Deepened in 1884 by a Lobnitz dredger, with cutting rams of 3½ tons, rock removed in layers 20 in. thick, and the breaking up cost was 7*s.* 3½*d.* per yd. cube.

The canal was further deepened to 31 ft. in 1897 by a Lobnitz Rock-cutter with cutting rams of 13 tons, the average thickness of rock shattered was 31 in., and the average cost, including repairs and depreciation, was 1*s.* 4*d.* per yd. cube. Cost of raising the rock by dredgers and carrying it away in addition.

ELECTRIC POWER STATIONS.

Town.	Total Cost.	Cost of Land and Buildings.	Kilowatts Housed.	Cost of Buildings per Kilowatt.	Total Cost per Kilowatt.
	£	£	No.	£	£
Brighton	717,738	149,431	5,400	28	133
Bristol	671,616	53,550	9,050	6	74
Chichester	20,000	600 not land	200	3	100
Glasgow	1,368,134	211,172	10,993	19	124
Hackney	280,982	42,394	3,372	13	83
Metropolitan	1,802,383	435,777	18,500	24	97
Newcastle	1,192,442	169,675	20,000	8	55

	£	£	
Electric light installations for cities and towns, with buildings, plant, and mains complete		80 to 130	per kilowatt.
	3 ,,	5	per c.p. lamp.
Steam plant power stations		24	per kilowatt.
Oil plant power stations	23 ,,	25	,,
Capital cost of generating stations		20	,,
Power and electric stations generally, brick, exclusive of plant and machinery. 10*l.* to 25*l.* per kilowatt			6*d.* to 8*d.* per f.c.
Aldershot electric lighting station (1902). Brick walls and slated roof			6½*d.* ,,
Curragh electric light generating station (1913–14). For three 100-h.p. Diesel oil engines, 66 kilowatts per engine, with a 750 ampere hour battery and accessory machinery. Contains a basement for engine beds, silencer chamber, and oil-fuel store, and above, on ground level, an engine-room, battery-room, store-room, two offices, and lavatory. Brick walls in cement mortar, 1 to 3, concrete foundations, engine beds and floors, steel sashes, steel roof, boarded and covered with asbestos slates. 99,700 feet cube. Building only, exclusive of plant and machinery. Total, 2,080*l.*			5*d.* ,,
Building, including plant and machinery. Total, 7,456*l.*			1*s.* 6*d.* ,,
Cost of foregoing per kilowatt housed, 10*l.* to 38*l.*			
Extension to Curragh electric light station (1920–21). For one additional 100-h.p. Diesel oil engine and plant, 66 kw., the extension of engine-room and exhaust pit being 12 ft. long, and same width and height as existing building. Construction also similar. A corrugated iron workshop, 18 ft. × 12 ft., is attached to the end of the brick extension, and included in total cost and cubing. Lump sum tender for both together. 17,600 ft. cube total. 17*l.* external services in addition. Building only, exclusive of plant and machinery. Total, 2,188*l.*			2*s.* 5½*d.* ,,
Building, including plant and machinery. Total, 5,188*l.*			5*s.* 10¾*d.* ,,
Cost of foregoing per kilowatt housed, 33*l.* to 79*l.*			
East Ham electric power station, including tramway sheds and offices. Built by direct labour under the borough engineer. Total, 26,020*l.*			5½*d.* ,,
Salisbury engine-room and boiler-house (1904). Brick walls and slated roof, concrete floors			6½*d.* ,,
Usual charges for current for electric lighting			2*d.* to 3*d.* per unit.
Ditto for heating and power purposes			1*d.* to 2*d.* ,,

Engineering Factories.

Engineering factories, brick, exclusive of machinery (1930)			1*s.* to 1*s.* 6*d.* per f.c.
Material		50	per cent.
Labour		40	,,
Power		5	,,
Other costs		5	,,
		100	,,

Esplanades.

Marine Drive, Scarborough (1905).—Road 40 ft. wide, parade 20 ft. wide, and sea-wall 20 to 40 ft. high. Of concrete, on deep filling at base of cliff. Length, 1,400 yds. Total, 102,400*l.*, or 73*l.* per yd. run.

Excavating (Mechanical).

Methods.—Mechanical excavating greatly saves in labour, time, and cost over hand digging by pick and shovel, and may be classed under ten heads:

1. Steam shovels.
2. Trench-diggers.
3. Grab buckets.
4. Chain bucket excavators.
5. Drag-line excavators.
6. Scrapers.
7. Derricks and cranes.
8. Radial loaders.
9. Paving breakers.
10. Soil Transport.

1. *Steam Shovels.*—Steam shovel or steam navvy excavating for large masses of earth or rock in canals, docks, railway cuttings, etc., including filling wagons for removal. The buckets scoop

upwards with a general capacity of 1 to 3 cubic yards. Average output and pre-war costs of a 1½ cubic yard bucket steam excavator :—

	Yds. Cube
Ordinary soft soils	60–90 per hour, at 3*d.* to 4*d.* per yd. cube.
Stiff clay or gravel	40–50 „ „ 4*d.* „ 6*d.* „
Strong ground or soft rock	30–40 „ „ 7*d.* „ 9*d.* „

Manchester Ship Canal (1887-94).—Forty-two million cubic yards of excavating in sand, clay, gravel, etc., and 10 million cubic yards in sandstone rock. Average quantity for each steam navvy was 700 yds. per 10-hour day, or 70 yds. per hour, and cost 2d. per yd. cube, exclusive of cost of plant, depreciation, repairs, superintendence, etc.

Pre-war costs excavating and loading into wagons, 2*d.* to 6*d.* per yd. cube ; the harder the material the greater the saving. In easy soil as low as 1*d.* per yd. cube, including interest, depreciation, and repairs, but this is exceptional ; in stiff clay 2*d.* or 3*d.* ditto. Costs per yard cube are higher for small machines owing to the comparatively small output, and less for larger machines with big output.

Analysis of Costs.—Assuming a steam-driven crane navvy with 20 ft. jib centre and ¾ cu. yd. bucket capacity is getting out clay at the rate of 30 yds. cube per hour, the costs (August 1922) would work out to approximately as follows, including excavating and dumping into clients' wagons :

Output per day = 30 yds. cube per hour × 8 hrs. per day = 240 yds. cube.

	s.	*d.*
Working costs per day—		
One driver upon the machine	12	0
One boy as fireman	5	0
Two men assisting on ground at 8*s.* each.	16	0
8 cwt. coal at 35*s.* per ton	14	0
Oil waste and stores	3	0
	50	0
240 yds. cube.		
Rate per yd. cube	0	2½

	s.	*d.*
Add capitalised cost, including depreciation at 10 per cent. per annum, interest 5 per cent. per annum, and maintenance 2½ per cent. per annum, making a further	0	1½
Total capitalised cost per yd. cube	0	4

With an output of 80 yds. cube per hour for loose material the cost would be 2*d.* to 3*d.* per yd. cube.

On bigger productions the cost per yard cube comes down owing to the working rates being practically the same with the exception of a slight increase in coal consumption, so that on the larger machines the value would be well below the figure given. Fewer men are needed with electric power, or if caterpillar tracks are fitted.

Removing earth cover with a No. 6 ' Ruston ' crane navvy for the United Brick Co., Peterborough, came to 3¾*d.* per yd. cube. This previously cost 1s. 6d. per yd. cube by hand labour.

A 45-ton Wilson's steam-crane ' Jubilee ' excavator will work a clear 22-ft. face, and drive a gullet 45 ft. wide, and can travel forward in 30 seconds as each advance is made.

Weight of Machine.	Capacity of Bucket.	Lift of Crane.	Depth of Cut.	Output per Hour based on 10-hour day.
tons.	cub. yd.	tons.	ft.	yds. cub.
17	¾	3	16	25–45
20	¾	4	16	30–50
25	1	5	18	40–70
30	1½	8	20	60–100
45	2½	15	22	100–140

Pre-war cost was 1*d.* to 6*d.* per yd. cube delivered into wagons.

The ' Erie ' revolving steam shovels are built in two sizes, and can be fitted with broad traction wheels, rail wheels, or caterpillar tread, and will climb 25 per cent. grades under their own power.

Type ' A ' is used for stiff clay, gravel, or lighter shales, and Type ' B ' for stiffer clay, gravel, heavy rock shales, or blasted rock. The following rates of output are conservative and have often been exceeded. The yield depends upon plant management, and to keep the shovel busy ample hauling equipment is essential. To dig and load by pick and shovel costs seven times as much as the same amount with an ' Erie.'

Standard Type.	Capacity of Bucket.	Working Weight.	Approx. Price, August, 1922.	Output per hour, ordinary conditions.
	cu. yd.	tons.		cu. yds.
A	½	13	£1,800	15–25 shallow cuts (10 in. to 24 in.) 30–40 deep cuts (3 ft. or over)
B	¾	19	£2,070	25–35 shallow cuts (10 in. to 24 in.) 50–60 deep cuts (3 ft. or over)

Two hundred to 300 yds. cube per day is good going in a trench cut, which may be 19 ft. deep. One ' Erie ' ditcher does as much as a 50-man gang in clearing sides and keeping cuts ditched.

Analysis of Costs.—The following approximate working costs per day (August, 1922) are based on 200 working days per annum of digging and filling wagons or trucks with a Type 'A' ' Erie ' revolving shovel. The figures do not include any team or truck time.

	£	s.	d.
One driver or operator	0	15	0
One fireman	0	10	0
Two groundmen at 12*s.* 6*d.* each	1	5	0
Oil and fuel	1	0	0
Daily interest on capital invested, cost of machine £1,800 at 6 per cent.	0	10	10
Daily depreciation, say 10 per cent.	0	18	0
Total capitalised cost per working day	4	18	10

And £4 18*s.* 10*d.* per day ÷ 200 yds. cube output per day . . 6*d.* per yd. cube.

(Output variable according to soil, shallow or deep cuts, wagon service, etc.) 300 " " " . . 4*d.* "
400 " " " . . 3*d.* "

For a Type ' B ' shovel the approximate working costs per day would similarly be:

	£	s.	d.
One driver or operator	0	15	0
One fireman	0	10	0
Two groundmen at 12*s.* 6*d.* each	1	5	0
Oil and fuel	1	1	0
Daily interest on capital invested, cost of machine £2,070, at 6 per cent.	0	12	6
Daily depreciation, say 10 per cent.	1	2	0
Total capitalised cost per working day	5	5	6

And £5 5*s.* 6*d.* per day ÷ 300 yds. cube output per day . . . 4½*d.* per yd. cube.

(Output variable according to soil, shallow or deep cuts, wagon service, etc.) 400 " " " . 3½*d.* "
500 " " " . . 2½*d.* "
600 " " " . . . 2*d.* "

The ' B ' ' Erie ' with 4-men crew (driver, fireman and two groundmen) is equal on deep cuts to 50 or more labourers, and on rock loading to 20 or 30 men. Assuming a labourer gets 1*s.* 3*d.* per hour, and can dig and throw into wagons ½-yd. cube per hour, this is equivalent to 2*s.* 6*d.* per yd. cube for hand labour. That is, 50 labourers × 4 or 5 yds. cube each per day = 200 to 250 yds. cube per day for the gang, whereas the Shovel will excavate 500 to 600 yds. cube per day and lift into wagons at a cost of about 2½*d.* per yd. cube.

Two loads of a ' B ' ' Erie ' dipper or bucket will completely fill an ordinary 1¼ cub. yd. wagon and three ditto a 2 cub. yd. wagon.

Wagon Service.—There is no waiting with steam shovels, as the buckets or dippers lift ¾ to 2, or even up to 6 cu. yds. in one bite, and the spoil is at once tipped into trucks or wagons and removed on rails with a minimum loss of time. One steam excavator requires at least one locomotive to look after it, with a speed not exceeding 8 to 10 miles per hour for sets of 30 to 40 wagons, and stops of 15 to 20 minutes not more than 4 miles apart for 'fatting.' Allow ½ hr. at one end and ½ hr. at the other for running round the wagons, getting coal and water, and shunting out crippled ones. Steam-driven end-tipping wagons hold 2½ cu. yds. and side-tipping wagons 3 cu. yds., measured in the solid. Maintaining them in good running order costs, pre-war, ¼*d.* to 1*d.* per yd. cube per mile.

Generally, it takes 45 side wagons to keep a steam excavator going, if the haul is not more than 1¼ miles, and gradients are such that a 12- or 13-in. locomotive can handle 20 wagons in a set.

Expenses of operating a locomotive depend on water (mostly), gradients, and coal. The pre-war labour cost of driving and repairing a locomotive is £1 per shift, including fitters and smiths. To this add foreman, boy turning points, general expenses 30 per cent., interest and depreciation, 1 ton of coal, repair accounts, water, oil, and stores, or £2 10*s.*, making a total cost per shift of £3 10*s.* Washing and repairing engine while in shed adds 20 per cent. to wages paid for actual driving.

2. *Trench-diggers.*—The advantages compared with hand labour are economy, speed, ease of control, and ready supervision. The cost is less than half that of hand labour, and the deeper the trench the greater the saving. If a labourer can excavate and throw out by hand ½ yd. cube per hour in trench work it will take 120 men to yield a total output equal to one No. 36 machine, which can dig 1 yd. cube per minute or 60 yds. cube per hour.

A 'Parsons' trench excavator, operated by petrol or steam, can dig a trench as detailed below. The prefix numbers indicate the maximum width in inches to which that particular machine will cut, and it will excavate any depth up to that mentioned.

Machine.	Working Weight.	Width of Trench.	Depth.	Rate per Minute.
	tons.	ins.	ft.	
No. 24	8	15, 18, 24	10	8 ins. to 10 ft.
No. 36	14	20 to 36	15	6 ins. to 10 ft.
No. 78	24	28 to 78	20	1½ ins. to 4 ft.

3. *Grab Buckets.*—Grab buckets are employed when it is impracticable to use a steam shovel or trench-digger, and they can be operated by a special crane, or by attaching to an ordinary steam crane or derrick. The common type is known as the clam-shell grab, which has jaws opening in and out. Capacity varies from ¾ to 3 cu. yds., and 20 to 30 cycles per hour of grabbing, raising and swinging round, and discharging can be performed. The cost is about half that of hand labour, and the saving is greater when under water. When dredging Limerick harbour with a Priestman's grab the average pre-war cost of dredging and discharging was 1⅞*d.* per ton.

4. *Chain Bucket Excavators.*—This excavator consists of a bucket ladder which scoops up material and discharges it into wagons either above or below the engine. The machine is best for a definite profile, such as a railway cutting or reservoir, but the ground must be free of rock or boulders. A good size weighs 40 tons, and digs to 20 ft. deep or more at theoretically 190 cu. yds. per hour, but the actual output is about 66 per cent. of this rate.

5. *Drag-line Excavators.*—Generally speaking, drag-line and cable-line excavators are used for cuttings of large size for drainage purposes, for canals, handling sand and gravel, and in some instances for preliminary road work over rough ground. These excavators can proceed in any direction from railway station to works or from one job to another.

Bucket capacity 1 cu. yd., weight of machine 26 tons.
" 2 " " " 62 "
" 3 " " " 75 "

The cableway drag-line excavator has two masts, known as the head tower and tail tower, with track cable between, along the line of which the bucket runs. Buckets, 1½ cu. yds. With an average haul of 225 ft. cost was 5*d.* per yd. cube, including maintenance, repairs, fuel, supervision, and depreciation.

6. *Scrapers.*—Two types, 'drag scrapers' and 'wheel scrapers.' These are widely used in America for shallow excavation and grading work, and are drawn by one horse and one man, or by two horses and two men. The surface is first cut up with an ordinary plough, and the scraper then dragged over the ground to remove the loosened soil. Capacity of a drag scraper is about $\frac{1}{3}$ cu. yd.—wheel scraper much greater, about $\frac{1}{2}$ cu. yd.

7. *Derricks and Cranes.*—Contractors' locomotive or 'loco' steam cranes may weigh from 10 to 60 tons, and lift loads up to 25 tons, with a jib radius of 16 to 25 ft. The cranes have 'all motions,' *i.e.* lifting, lowering, revolving, jib adjusting, and travelling on rails with a gauge of 4 ft. 8½ ins. to 12 ft.

Stationary or travelling steam cranes may be employed to work iron or flat-bottom wooden skips, which are like large buckets or open boxes respectively, and hold $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, 1 cu. yd., or more, made to discharge from the crane over a wagon. Woodford's patent steel bucket skips are excellent, self-righting, and with safety catch.

8. *Radial Loaders.*—These are used for raising loose soil from the bottom of an excavation to the surface level, and have a chain of buckets attached to an inclined arm or boom, and a shoot, and are driven by an electric motor or a petrol engine. The usual capacity is 1 cu. yd. per minute, and the machine can load a 7-ton wagon in 7 mins. Cost of handling soil by this method is 1*d.* to 6*d.* per yd. cube.

The Haiss wagon-loader is a labour-saving device for dealing with loose materials, supplied by Millar's Machinery Co., Ltd., Pinners' Hall, London. It is a self-propelled petrol-driven machine fitted with a bucket elevator, operated by one man, and can load 5 cu. yds. into a truck in five minutes.

The saving in loading cost will enable a contractor to quickly regain the expenditure on these appliances.

9. *Paving Breakers.*—Breaking up old macadam, concrete, or paving was formerly done by steel wedges, sledge hammers, and crowbars by hand labour, but these are tedious and expensive compared with mechanical means.

Pneumatic paving-breakers show a cost saving of as much as 65 per cent., and a time saving of 75 per cent., over hand methods. These percussion tools are operated by compressed air from a portable compressor, driven either by petrol or electricity, which will work two to five large picks.

Weight.	Length overall.	Size of Steel.	Hose.	Air pressure.
lbs.	ins.	in. hex.	in.	
60	24½	1½	¾	Over 80 lbs.
69	26¾	1⅝	¾	Under 80 lbs.

The steel cutters are of two kinds—one with a chisel edge, and the other with a moil point. An ordinary gang consists of three men—one compressor man and two breaker operatives. Each operative can break up an average of 245 yds. sup. of 9-in. concrete per day. Cost of running plant in oil and fuel is about 2*s.* per hour. Breaking up concrete surfaces, 8 to 20 ft. wide and 9 ins. to 12 ins. thick, in London streets, was 2*s.* 6*d.* per yd. cube, based on one portable compressor working four or five large picks.

One man with one paving breaker can smash up as much old tarmac on concrete roads for cutting trenches, etc., as nine men handling wedges and sledge hammers. Removing the top layer of a road came to 6*d.* per yd. sup. against 2*s.* per yd. sup. for burning and picking off.

10. *Soil Transport.*—It is impossible to maintain a big output with excavating equipment unless the surplus soil can be removed as quickly as the digging is done. Speed obviates the large number of trucks or wagons caused by slowness. Careful planning is required for rails, wagons, dumps, etc., and good organisation.

The types of transport may be classified as—

(*a*) Hand labour small receptacles, such as wheelbarrows or buggies.
(*b*) Horse-drawn vehicles, wagons or carts.
(*c*) Steam-driven wagons.
(*d*) Petrol-driven wagons.
(*e*) Narrow-gauge track with wagons.
(*f*) Standard-gauge track with trucks.
(*g*) Electrically driven trucks and vehicles.

(*a*) *Hand Labour.*—Net unit cost per ton-mile about 7*s.* 6*d.* (February 1922), for removal including loading up, wheeling, levelling, and return of empty, reckoning interest on initial outlay, depreciation, and maintenance.

Assume one man will do the equivalent to 10 ton-miles per week of 44 hrs. Output low and unit cost high, as many journeys are needed to transport a ton.

(*b*) *Horse-drawn Vehicles.*—1*s.* 6*d.* per ton-mile under ordinary average conditions, so this is very economical compared with hand labour, or only one-fifth cost. It is also a flexible system, as horses and vehicles can be hired, but is not sufficient for extensive excavation schemes. Tip-carts or tip-wagons are necessary, and the tipping can be done by a lever at the seat of the driver.

(*c*) *Steam-driven Wagons.*—The haulage costs of these may be divided into standing charges, which are constant, and running costs, which are governed by mileage. The costs per mile (July 1921) work out as below, including standing charges of insurance, rent, interest on first cost, licence, registration, and wages; and running costs of fuel (coal, coke, or petrol), lubricants, tyres, repairs, maintenance, depreciation on 'life,' etc., based on 200 miles per week, although 400 miles or more may be accomplished. The fuel-consumption basis, plus 20 per cent. for wastage, is 55*s.* per ton for coal or coke, and 2*s.* 8*d.* per gallon for petrol.

Unit.	4-ton Steam.	4-ton Petrol.	6-ton Steam.	6-ton Petrol.	10-ton Steam and Trailer Combination.
Cost per ton-mile	4¾*d.*	6*d.*	3½*d.*	4¾*d.*	2½*d.*
Fuel mileage .	20 miles per cwt.	7 miles per gal.	15 miles per cwt.	5 miles per gal.	13 miles per cwt.

Life of a steam wagon without trailer is taken as 12,000 miles.
" petrol lorries is 25 per cent. less, say . 9,000 "
" wagon tyres with trailer . . . . 7,000 "
" trailer tyres . . . . . 12,000 "

In calculating the depreciation allowance—

Life for a steam wagon without trailer is taken as 150,000 miles.
" steam wagon with trailer . . . . 120,000 "
" petrol lorries . . . . . 100,000 "

The cost shows considerable saving over horse-drawn vehicles at 1*s.* 6*d.* per ton-mile. In fact, the expense of transporting 4 tons 1 mile by steam wagon, 4¾*d.* × 4 = 1*s.* 7*d.*, is practically equal to that of 1 ton only the same distance by horse wagons.

The output of a 4-ton steam wagon with a speed of 8 to 10 miles per hour will run to 800 ton-miles per week, equivalent to 80 men by hand labour. To justify the initial outlay of an end- or side-tipping wagon at £1,200 over a horse and cart, it should go 24,000 ton-miles to make the necessary saving, which is easy considering that its estimated life is 300,000 ton-miles of work to be performed. With several steam wagons the gain is enormous, and the economy of employing them on large works amply justified.

(*d*) *Petrol-driven Wagons.*—A steam wagon is best for transporting a maximum tonnage over a maximum distance in a minimum time at a minimum cost; but for maximum mobility with lighter loads and for special suitability for intermittent work, the petrol vehicle has undisputed claims, though its working costs are necessarily higher.

An investigation into the actual working records of 100 steam wagons by five different makers, and of 100 petrol vehicles by nine leading makers, showed that the average cost (1920) for hauling 5 tons per mile worked out at:—

For steam wagons, 1*s.* 5½*d.*, or 3½*d.* per ton-mile.
For petrol vehicles, 2*s.* 10½*d.*, or 7*d.* per ton-mile.

These rates included all overhead charges, 12½ per cent. depreciation, interest, fuel, wages, repairs, etc., over 15 million ton-miles. The annual saving of each steam wagon compared with petrol was over £1,000. Steam wagons gave steadily consistent figures, whereas petrol lorries varied widely.

Usual capacities of tipping petrol wagons are 1½, 2, 3, 4, and 5 tons, but 2 tons is the most useful. Cost per ton-mile, 6½*d.*, based on 300 miles per week, including depreciation, interest on capital, wages, tyres, renewals, fuel, etc.

(*e*) *Narrow-gauge Track with Wagons.*—Transporting surplus soil in side-tipping wagons on a narrow-gauge track is, under general conditions, more economical and far superior to ordinary manual labour with small receptacles or to horse-drawn carts. The track is commonly known as 'Jubilee,' industrial, or contractors' track, and the wagons as 'Jubilee' wagons. It is a portable railway with steel rails (10 to 20 lbs. per yd.) and corrugated steel sleepers, and the lay-out should be well planned. The tip wagons (½ to 7 cu. yds.) can be managed by hand labour, horses, or light locomotives.

Cost for hand-operated wagons on a level railway is 1*s.* 3*d.* per ton-mile.
„ horse-drawn „ „ „ 0*s.* 3*d.* „

Comparative costs for the different methods of transport:—

	s.	*d.*	
(*a*) Hand labour with wheelbarrow	7	6	per ton-mile
(*b*) Horse and cart	1	6	„
(*c*) Steam wagons, average	0	3½	„
(*d*) Petrol vehicles, average	0	7	„
(*e*) Hand-operated wagons on industrial track	1	3	„
(*f*) Horse-drawn „ „ „	0	3	„

Steam wagons are, therefore, cheapest for large quantities over considerable distances, and the industrial track (with horse labour) for small or large quantities over short distances.

(*f*) *Standard-gauge Track with Trucks.*—This system is restricted, as the first outlay is expensive, and the method is not so flexible as light railways. Large tipping wagons will be necessary, and no cost figures can be given, as the mode of transportation is for special circumstances.

(*g*) *Electrically-driven Trucks and Vehicles.*—These have not been extensively developed up to the present, but they are useful for short haulages and when continual stopping and restarting are unavoidable.

Taking a standard make of 5-ton electric vehicle, the 'fuel' cost at 2*d.* per unit works out at 2⅝*d.* per mile, with loads from 4 to 5 tons. Running costs, including interest at 6 per cent., depreciation at 10 per cent., tax, insurance, wages, charging current, rubber tyres, oil, grease, batteries at 5 years' life, etc.:—

Weekly mileage.	Load carried.	Annual Cost.	Running Cost.
	tons.	£	per ton-mile.
100	2	482	11½*d.*
100	3	482	7½*d.*
140	4	515	4½*d.*
140	6	515	3*d.*

Electrical traction on industrial or light railways, running costs 1½*d.* per mile.

Electric locomotives (costing about £450 per vehicle, complete with battery) will haul a load of 10 tons on a level track, and one charge of battery will give a normal run of 20 miles. One charge takes 14 units of electricity at 2*d.* per unit, which works out to 1½*d.* per mile run.

An electric locomotive can economically pull wagons on a narrow-gauge track in lieu of manual or animal labour, with great saving of time. The comparatively small capital will soon be recovered. The advantages are—reduced first cost, easy control, efficiency, flexibility, and low expenses of operation, upkeep, maintenance, and depreciation.

GAS WORKS.

Gasworks.—Gasworks complete, including buildings, plant, and distributing mains:

Estimated costs, 1930.	Small Towns.	Large Towns. or Cities.
Per head of population	40*s.* to 60*s.*	50*s.* to 80*s.*
Per ton of coal carbonised per annum	7*l.* to 10*l.*	9*l.* to 12*l.*
Per million cubic feet of gas produced per annum	700*l.* to 900*l.*	900*l.* to 1,200*l.*

Land.—Area of land for the erection of works at least 2 acres per million cubic feet of gas per maximum diem.

Proportionate Capital Expenditure.—Including works, distribution plant, etc.:—

On buildings and works	38	per cent.
On district mains	55	„
On Parliamentary, promotion and engineer's expenses	7	„
	100	

Proportionate Cost of Parts.—Including buildings and plant :—

Retort house, including benches, fireclay retorts, etc.	25 per cent.
Purification buildings, with purifiers, gas scrubbers, etc.	30 ,,
Gasholders, iron or steel, with guide framing, brick-lined tanks, concrete bottoms, and excavation	40 ,,
Station meter-house, meter, and miscellaneous	5 ,,
	100

Retort-houses.—Including foundations and brickwork to benches, etc. :—

Exclusive of plant or machinery (1930)	9*d.* to 1*s.* per f.c.
Including retorts, ironwork, and fittings (1930).	2*s.* to 4*s.* ,,

Glover-West's system for vertical gas retorts, Belfast (1913) :—
70,950*l.* for a plant to carbonise 480 tons of coal per 24 hours,
=148*l.* ,, ,, ,, 1 ton ,, ,,

Gasholders.—Steel or iron telescopic holders, including guide framing, etc. :—

Estimated costs, 1930.	Per 1,000 cub. ft. of capacity. £ £
Single-lift holders, up to about 50,000 cub. ft.	50 to 70
If of the spiral type, 25 per cent. less	38 ,, 53
Two-lift holders, about 250,000 cub. ft. capacity	30 ,, 40
If spirally guided, about 50 per cent. less.	15 ,, 20
Large holders, from 2 to 3 million cub. ft. capacity	18 ,, 30
The 10½-million holder at Manchester cost (pre-war)	5
The 12-million holder at East Greenwich Works cost (pre-war)	5 guineas.

GROYNES.

There are four types of groyne construction in this country—timber, concrete block, reinforced concrete, and chain cable. Cost of timber groynes for the seashore, comprising creosoted fir piles with horizontal sheeting bolted thereto, and stiffened with ties and struts. Piles well driven into sand or shingle, and executed as tide-work. Pre-war costs :

Light timber groynes, 1*l.* to 3*l.* per yard run.
Heavy ,, ,, 3*l.* ,, 6*l.* ,, ,,

The following particulars have been condensed from *Marine Works*, by E. Latham, M.Inst.C.E. (1922. 16*s.* Crosby Lockwood & Son, London), and the other books mentioned in each case. The first five examples are pre-war, and the last post-war.

	Cost per yd. run. £ *s.* *d.*
Bridlington.—Low timber case groynes, constructed of pitch pine piles, shod with 18-lb. pile-shoes, driven 8 ft. into the boulder clay in pairs, at 7 ft. 6 in. centres. 11 in. × 4 in. pitch pine planking inserted between the piles, so that a depth not exceeding two planks projects beyond the sand level. Timber all creosoted. Groynes spaced at a distance apart not exceeding their length, which was about 200 ft. First four groynes cost	2 14 0
Most of the others cost	1 16 9
For details see *Coast Erosion and Protection*, pp. 114–115, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London.)	
Eastbourne.—Timber groynes erected about 1886–96, some 70 yards apart, at right angles to the foreshore. Constructed of 9 in. × 9 in. pitch pine and oak piles, 6 to 16 ft. long, driven to an average depth of 9 ft., set 4 ft. 6 ins. apart, centre to centre, with walings 8 ins. × 6 ins. and 6 ins. × 6 ins. Planks, 9 ins. × 2 ins., are spiked to the piles in lengths of 20 ft. and over, to span four bays and break joint. Large oak land-ties fixed at right angles to the piles, and fastened to a smaller pile at back. The majority are high groynes, and were originally 8 to 10 ft. in height at shore end, and about 4 ft. at low end, and did not extend to low-water mark. The more recently constructed groynes vary from 4 ft. high at the land end to 2 ft. at low-water mark. Average length 100 yards, and cost 375*l.* each, or	3 15 0
Seven case groynes erected to the east of the pier in 1897. Pairs of 9 in. × 3 in. pitch pine piles, spaced 7 ft. 6 in. centres, with 9 in. × 3 in. planks inserted between. Average length 100 yards, and cost 68*l.* 15*s.* each, or	0 13 9
For details see *Coast Erosion and Protection*, pp. 104–106, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London.)	
Lowestoft (1901–1903).—North Denes. Four timber main groynes, three having a length of 290 ft., and the fourth 340 ft., spaced 1,500 ft. apart. Shoreward ends 4 ft. above high-water level, and seaward ends 3 ft. below the same level. For details see *Proceedings of the Institution of Civil Engineers*, vol. clxxxv. p. 106	22 1 3

	£	s.	d.
Southwold.—Timber groynes. For details see *The Protection of Sea Shores from Erosion*, p. 23, by A. E. Carey, M.I.C.E.	4	4	0
Withernsea (1873).—Six timber groynes consisting of 13 in. piles, 22 ft. long, 5 ft. apart, driven down 12 ft., with 11 in. × 4 in. planks, 13 in. × 6½ in. struts, and foot piles. Four are 300 ft. in length, and two 350 ft. Only three planks project above sand-level. For details see *Proceedings of the Institution of Civil Engineers*, vol. clix. p. 73	3	7	6
Blue Anchor (1921).—On the Bristol Channel, and in front of the Minehead to Watchet Road, north Somerset. Groyne 600 ft. long and two timber stockades, each 1,500 ft., parallel to existing sea-wall. Stockades consisted of 10 in. × 10 in. main piles of pitch pine, with 9 in. × 4 in. intermediate piles bolted to continuous walings. Half of total length of stockades had to be constructed by bedding the piles in mass concrete, necessitating trenching in rock. Engineer, E. Latham, M.I.C.E. Contractors, Messrs. John Cochrane & Sons, Westminster. Total about 30,000*l.* Cost per yd. run includes stockades	25	0	0

Harbours.

Artificial harbours complete, including reclamation of land, dredging, enclosure walls, breakwaters, landing stages, lighting, buoys, cranes, etc. Estimated costs, 1930 :—

10,000*l.* to 20,000*l.* per water acre enclosed.

Colombo Harbour (1874–1914).—On the west coast of Ceylon and entirely artificial. It ranks twelfth among the greatest seaports, and there is ample space for 50 steamers besides smaller craft. The enclosed area is 650 acres (over a square mile), and depth 30 to 36 ft. at low water. Rise of tide at Ceylon is only 2 ft.

South-west breakwater, 1874–85, is 4,212 ft. long, built of concrete blocks weighing 18 to 30 tons on the sloping bond system, and cost 705,200*l.*, or 167*l.* per ft. run. Extension to ditto as a further protective arm, 1907–12, is 1,800 ft. long, also of concrete blocks, and cost 380,000*l.*, or 211*l.* per ft. run. North-east breakwater, 1894–7, is 1,100 ft. long, and constructed as a rubble embankment; the north-west or island breakwater, 1900–6, is 2,657 ft. long, and made of concrete; the two together cost 500,000*l.*, or 133*l.* per ft. run. Total length of the four breakwaters about 9,770 ft., with 5 lighthouses on them, and total cost 1,585,200*l.* Graving dock, 1900–4, is 700 ft. long, 85 ft. wide, and cost 400,000*l.*; patent slip, 1900–3, is 800 ft. long, and cost 43,000*l.*; coaling depot, on 24 acres of reclaimed land, has a frontage of 2,200 ft. with 18 jetties, and cost 163,000*l.* Other services, 821,900*l.* Total expenditure from 1874 to 1914 (forty years) was 3,013,100*l.* The small Fishery Harbour immediately to the northward has a rubble arm 800 ft. long, and cost 12,000*l.* The engineers were Sir John Coode, Son, and Mathews; and the resident engineers, Sir John Kyle, M.I.C.E., Mr. J. H. Bostock, M.I.C.E., Mr. John Kyle. M.I.C.E. (son of Sir John), and Mr. A. D. Prouse, M.I.C.E.

4,636*l.* per water acre enclosed; 162*l.* per ft. run, average of breakwaters.

Dover Harbour (1898–1909).—Original Admiralty Pier, 1,000 ft. long, was built in 1847–71. Dover Harbour Board then constructed a small commercial harbour of their own in 1890, between the existing Admiralty Pier and a new east pier, of 56 acres net area, afterwards increased to 75 acres by reclaiming the foreshore. The National Harbour was proceeded with in 1898–1909, and comprised the extension of the western breakwater, or old Admiralty Pier, from 1,000 to 3,000 ft., an eastern arm, 3,320 ft., and an isolated breakwater in the middle, 4,200 ft. Total sheltering works, 9,520 ft., or nearly 2 miles long, with two entrances 740 ft. and 650 ft. wide and 42 ft. deep at low water, enclosing 610 acres, exclusive of the 75 acres in the Commercial Harbour. Height of breakwaters from bottom of foundation to parapet top 60 to 120 ft. or an average of 90 ft., with 50 ft. average depth below low-water level, and 50 ft. average thickness, built of concrete blocks, weighing 10 to 40 tons each and faced with granite above low-water level. Works include a sea-wall, 3,850 ft. long, to protect base of cliffs, a lesser sea-wall, 700 ft., and reclaiming about 20 acres of land. Engineers, Sir John Coode, Son & Mathews. Contractors, Messrs. S. Pearson & Son, Ltd. National Harbour, 610 acres, cost 4,000,000*l.*, and inside Commercial Harbour, 75 acres, 1,250,000*l.*, or a total of 685 acres and 5,250,000*l.*

National Harbour :	6,557*l.* per water acre enclosed ;	420*l.* per ft. run of breakwater.
Commercial Harbour :	16,666*l.* " " " ;	131*l.* " " "
The two combined :	7,664*l.* " " " ;	551*l.* " " "

Heating.

The fewer the radiators, and the longer the run, the higher the cost per radiator. 15 ft. sup. of radiator should be supplied for every 1,000 cubic feet of space to be heated. Cost includes fittings complete, but is exclusive of boiler-house and buildings (1930).

Heating buildings with boilers, pipes, and radiators	2*l.* to 8*l.* per 1,000 f.c.
Low-pressure hot-water heating and connections	15*l.* ,, 20*l.* per radiator.
Hot-water work inside a building, 3-in. and 4-in. pipes . . .	2*s.* ,, 3*s.* per ft. run.

Landing Slips.

Landing Slips, Milford Haven (1894).—Formed of Portland cement concrete, with shingle supplied by contractor, and 8 ft. wide × 3 ft. high, on 18-in. foundations. In tidework, and not exceeding 40 yards from shore. Excavation in boulders and shingle on beach. 30*s.* per foot run.

Lighthouses.

Lighthouse, Northern Point, Northern Province, Ceylon (1914–16).—Tower is supported on reinforced concrete platform over hardwood piles, and built of dressed coral stone in lime mortar, cement rendered externally. Walls 2 ft. 7½ ins. thick above plinth, carried up with a uniform thickness at a batter of 1 in 48. Internal diameter of tower 8 ft. 3 ins., and height from top of foundation to reinforced concrete cap 91 ft. Fourth order light visible for 16 miles, and focal plane 97½ ft. above mean sea level. Cost, exclusive of lantern and ironwork above the cap, 1,730*l.*, or 1*s.* 6*d.* per foot cube.

Lighting.—A complete gasworks plant for a lighthouse costs about 800*l.*

Annual expenditure for gas lighting, where works are installed . . . 72*l.* per light.
" " " " where gas is supplied from elsewhere . 32*l.* "

A first-class electric lighthouse installation, including optical apparatus, lantern, dynamos, engines, air compressor, siren, etc., but not buildings, costs about 6,000*l.*

Maintenance.—Average annual cost of maintenance of an English shore lighthouse, with two keepers, is 280*l.*

Average annual cost of maintenance of an English shore lighthouse, with three keepers and a siren fog signal, is 450*l.*

Annual maintenance of a rock lighthouse, with four keepers and an explosive fog signal, is about 800*l.*; and of an electric light station, 1,100*l.*

Lightships.—Steel lightships, of average size, with power-driven compressed air siren, cost about 16,000*l.*

Annual maintenance of ditto, including periodical overhaul, 1,320*l.*

Usual limits.—Length . . . . . 80 to 114 ft.
Beam . . . . . 20 " 24 "
Depth moulded . . . . . 13 " 16 "
Tonnage . . . . . 155 " 280 "

LIGHTING.

Buildings.—Cost of gas and electric lighting inside buildings, including service pipes, stopcocks, ordinary brackets, pendants, switches, wiring, and other articles, fixed complete, but excluding meters, external gas mains, generators, etc.

	s.	s.	
Acetylene	20	to 40	per light.
Coal gas	30	„ 50	„
Electric	25	„ 50	„

Wiring, including all necessary wire, switches, fuses, lamps, holders, casings, etc., but not electroliers or shades, 15*s.* to 40*s.* per lamp.

Installing artificial lighting per 100 points, including oil-engine, dynamo, wires, lamps, etc., but excluding buildings:

Acetylene.	Petrol Gas.	Electric Light.
100*l.* to 200*l.*	150*l.* to 200*l.*	200*l.* to 300*l.*

Acetylene.—Cost of upkeep consists mainly in the purchase of carbide with occasional renewal of burners. A 25 c.p. burner of ordinary type consumes about 1 f.c. of gas per hour, which demands ½ lb. carbide. With calcium carbide at 15*s.* per cwt. the cost of such a burner works out at ¾*d.* per hour. Total upkeep of a 100-light installation is between 20*l.* and 30*l.*, according to number of hours lights are used.

Gas Lighting of the Castle, Carlisle (1896).—Supply from City of Carlisle Gas Company's mains through a 600-light dry meter supplied by Company. 4 in., 3 in., and 2 in. cast-iron mains and 1½ in. to ½ in. galvanised wrought-iron service pipes, underground pipes 3 to 3½ ft. deep. Fittings include 19 governors, 10 valves, 20 stopcocks, 10 dry meters, 572 burners, 10 Wenham lights, 12 Schulke lights, 20 Deimel lights, 18 Welsbach incandescent lights, 12 Sugg's lights, etc. Occupation of barracks, 731 adults and 72 married quarters.

Total, 1,144*l.* 36*s.* per light or point. 28*s.* per head.

Gas Lighting of Strensall Camp, near York.—Completed 1915, in extension of the York Gas Co.'s mains. Cost includes 3-in. external steel mains, 2 in. to ½ in. wrought-iron branches, brick meter-house and meters, siphons, stopcocks, burners, excavation, fixing, etc., complete, in huts and 40 married quarters for about 1,260, total of officers, N.C.O.'s, and men. 376 incandescent burners and 584 flat-flame burners, or 960 lights altogether.

Total, 1,780*l.* 37*s.* per light or point. 28*s.* per head.

Electric Lighting, Army Pay Offices, York.—Feb. 1915. 84 electric lights, mostly of 100 c.p. each, including opal glass shades, wiring, cords, switches, fuses, etc., but not cable into building or any plant, as taken from the Corporation electric main in road. 18 officers and 300 clerks.

Total, 91*l.* 22*s.* per light or point. 6*s.* per head.

Electric Lighting, Army Pay Offices Extension, York.—Aug. 1916. One-storey corrugated iron building, lined with plaster slabs. 136 electric lights, mostly of 100 c.p. and 50 c.p. metal filament lamps, including pendants, opal and holophane glass shades, wiring, cords, 109 switches, fuses, distribution boards, etc. Direct-current supply on the three-wire system taken from the Corporation electric main in adjacent road. 24 officers and 400 clerks.

Total, 137*l.* 20*s.* per light or point. 6*s.* 6*d.* per head.

Railway Coaches.—	£
Cost of fitting a railway coach with electric light	130
„ „ „ „ incandescent gas	34
Annual maintenance of an electric lit railway coach	13

Locks (1930).

Including foundations, invert, walls, gates, sills, machinery, lock-keeper's cottage, etc.

Brick and concrete	Per yd. cu. of internal capacity 50*s.* to 80*s.*
Stone and concrete	,, ,, ,, 80*s.* ,, 120*s.*
Canal locks	each 10,000*l.* to 20,000*l.*
River locks	,, 30,000*l.* ,, 50,000*l.*

Marine Piers.

Timber and iron piers for seaside places, with creosoted fir or iron screw piles, averaging 40 ft. long and driven up to 15 ft. in sand or shingle, including braces, ties, timber decking, railings, tarring, gates, ticket office, seats, etc., but exclusive of pavilion or band-stand.

Gangway or promenade portion	8*s.* to 12*s.* per ft. sup.
Landing stage or head to pier	10*s.* ,, 16*s.* ,,

Military Pier, Tilbury (1896).—450 ft. long by 16 ft. wide, or 7,200 ft. sup. Height above h.w.o.s.t. level, 4 ft., and above l.w.o.s.t. level, 20 ft. Foundation, 3 ft. of mud over 20 ft. of chalk, the distance bored. Substructure of wrought-iron piles, 10 ft. apart, with rod iron braces, on which are fixed wrought-iron girders with intermediate joists supporting timber decking. 18-in. gauge tramway rails, 24 lbs. per yard, and steam crane to lift 10 tons. Total cost, including 500*l.* for hoisting machinery, 3,200*l.*, or 8*s.* 11*d.* per ft. sup.

Batticaloa Jetty, Eastern Province, Ceylon (1900).—Timber pier, 50 ft. long, with return portion 22 ft. long, and 10 ft. wide. Cost, 5*s.* 6*d.* per ft. sup.

Galle Jetty, Southern Province, Ceylon (1916).—Jetty is 162 ft. long × 20 ft. wide, carried on concrete cylinders 6 ft. diameter, spaced 20 ft. centre to centre longitudinally and 14 ft. transversely, end pair being taken down to a depth of 20 ft. Special cylinders, 8 ft. diameter, form seats for two 3-ton cranes. Jetty is roofed for a length of 137 ft. Cost, 4,923*l.*, or 1*l.* 10*s.* per ft. sup. Cost of cylinders sunk, 6 ft. diameter, 3*l.* 19*s.*, and 8 ft. diameter, 5*l.* 3*s.*, per ft. run.

Kalkudah Jetty, Eastern Province, Ceylon (1901).—Jetty of iron, with wooden joists and planking, 165 ft. long × 28 ft. wide, and landings. Piles of H-iron section, 9 ins. × 7 ins., carried through a stratum of sand about 8 ft. into the coral bed of 1 to 2 ft. thick. Cross bracing, walings, fenders, etc. Corrugated iron roof over 122 ft. of length, supported on iron principals carried by H-iron standards, 8 ins. × 6 ins. Water 8 ft. deep at end of pier. Cost, including crane seat, 2,516*l.*, or 11*s.* per ft. sup. of platform area.

Paddiruppu Jetty, Eastern Province, Ceylon (1900).—70 ft. long with a tee head 30 ft. × 6 ft. wide, constructed of Palu timber with brick abutment. Cost, 8*s.* per ft. sup.

Mining.

(See Section XXXIX, p. 2555.)

Pile Driving.

(See p. 507.)

Railways.

Average cost of railways, main lines, 4 ft. 8½ in. gauge, double track, total capital expenditure including land and all charges :—

	£	£	
In England	35,000 to	45,000	per mile.
,, Scotland	25,000 ,,	35,000	,,
,, Ireland (5 ft. 3 in. gauge)	20,000 ,,	25,000	,,
,, Europe	15,000 ,,	25,000	,,

	£	£	
Main lines, construction work and stations only	10,000 to	20,000	per mile.
Light railways ,, ,, ,,	1,000 ,,	3,000	,,
Permanent way, single line, light construction, 4 ft. 8½ in. gauge, in flat country, cuttings and banks averaging 3 ft., rails 55 lbs. per yard, ballast 15 ins. deep, including stations and permanent works, but excluding land and rolling stock	5,000 ,,	6,000	,,
Ditto, heavy construction, 75-lb. rails, and 24 ins. ballast	6,000 ,,	8,000	,,
Yearly maintenance of permanent way	200 ,,	250	,,
Rolling stock, single line, depends on kind of traffic	700 ,,	1,000	,,
Permanent way, double line, in excess of above figures	50 ,,	75	per cent.
Rolling stock ,, ,, ,, ,, ,,	10 ,,	30	,,

Working expenses in England average 50 per cent. of the gross receipts.
,, ,, Scotland ,, 45 ,, ,, ,,
,, ,, Ireland ,, 40 ,, ,, ,,
Average gross receipts, 4*s.* to 6*s.* per train mile.

Railway Footbridges.—Of iron or steel, including foundations, supports, girders, floor, staircases, lattice sides, etc., erected complete, 5 ft. wide.

250*l.* to 350*l.* each, 30 to 40 ft. span, or 15*s.* to 20*s.* per ft. sup.

Railway Viaducts.—On the Great Western Railway there are a great many viaducts, especially in Cornwall, commencing at 50 to 60 ft. deep, and being as much as 90 or 100 ft., and even up to 150 ft., in the centre of the gorge. They are, as a rule, about 60 ft. spans between the piers, which is found to be the economical width. Segmental arches nearly, but not quite, semi-circular, 3 ft. thick at centre, and 3 ft. 9 ins. at the springing. Piers, 7 ft. 6 ins. wide at the top, tapering on every side at 1 in 32. This gives a pressure of about 8 tons per square foot on the masonry. The cost comes out for such a structure, carrying two lines of way, at 1*l.* per yard forward per foot high, measured from ground to rail. That is, for example, a viaduct 200 yards long, and averaging 70 ft. in depth, will cost 14,000*l.*

Avon Viaduct.—On the Midland Railway, and of brick. 720 ft. long, 51 ft. high, and 11 arches of 50 ft. span. Cost, 14,000*l.*, or 19*l.* per ft. run.

Congleton Viaduct.—On the Manchester and Birmingham Railway, and of stone. 3,080 ft. long, or over ½ mile, and 106 ft. high. Cost, 113,000*l.*, or 37*l.* per ft. run.

Dove Viaduct.—On the same line, and of brick. 1,716 ft. long, 88 ft. high, and 23 arches of 63 ft. span. Cost, 54,000*l.*, or 32*l.* per ft. run.

Viaduct over the River Eye, Berwickshire (1889).—Six openings of 50 ft. clear span, 55 ft. 3 ins. between centres of piers, and extreme height above bed of stream 60 ft. Total length of bridge 331 ft. and 15 ft. wide; single track. Abutments of 1 to 7 concrete. Five piers, 45 ft. high and 12 ft. wide at top, with 9-in. and 18-in. brick face and concrete hearting, and 9-in. brick wall up the centre. Superstructure of lattice main girders 8 ft. apart, with cross girders of 10-in. × 5-in. rolled iron joists, 40 lbs. per ft. run. Flooring of 4-in. planking, and the rails carried by longitudinal beams, 14 ins. × 12 ins. Cost, 3,700*l.*, or 11*l.* per ft. run, or 15*s.* per ft. sup.

Viaduct on the Gifford Light Railway, Haddingtonshire (1900).—Four spans of 42 ft. 8 ins., centre to centre of three piers, with 1 to 6 concrete foundations. Height to rail level above the bed of stream is 50 ft., and length over all 194 ft. by 18 ft. wide; single track. Masonry piers, haunches, and abutments, and brick arches over openings. Cost, 2,043*l.*, or 11*l.* per ft. run, or 12*s.* per ft. sup.

New York Elevated Railroad (1872–80).—Steam traction. Two lines of way supported on square wrought-iron lattice-work columns, let into cast-iron base blocks founded on brickwork and concrete, at distances of 37 to 44 ft. apart. Rails of Vignoles or flange pattern, of Bessemer steel, weighing 50 lbs. per yd. run, spiked to cross timber sleepers and guarded by longitudinal timbers. Sharpest curve is 90-ft. radius. Steepest gradient, 1 in 50 for a length of 800 yds.

Stations about ⅛ mile apart, with platforms 200 ft. long and 13 ft. wide. No payment was made for way-leave along the streets, nor for compensation to frontages. Length, 35 miles. Total cost, 2,870,000*l.* Cost per mile of double track :—

	£
Foundations, columns, girders, superstructure, and permanent way	57,696
Railway stations and platforms	12,000
Rolling stock, 5 locomotives and 12 cars	11,680
Per mile of double track	81,376

Tube or Underground Railways.—Electric traction, as constructed in London. Two tracks 4 ft. 8½ in. gauge, each laid in a separate tunnel, 11 to 12 ft. diameter. 300,000*l.* to 600,000*l.* per mile of double track.

	£
London (Central), 1891–1900, 6 miles, 13 stations	580,000 per mile of double track.
London (Waterloo and City), opened 1898, 1½ miles	340,000 „ „ „

Steam Traction.—Two tracks, 4 ft. 8½ in. gauge, laid in elliptical tunnel, 29 ft. wide and 17 ft. high, of 27 in. brickwork on concrete foundations.

	£
London (Metropolitan), 1863–84	600,000 per mile of double track.
London (Metropolitan District), 1864-84	250,000 „ „ „

Both the foregoing have since been converted to electric traction, completed in 1905. The Metropolitan has 32 electric miles, and the " District " 28 electric miles.

Cost of electrification only, exclusive of power stations, sub-stations, rolling stock, etc., 5,000*l.* to 10,000*l.* per mile of double track.

Cost of Indian Railways.—For the year 1895 the capital cost (rupee at 1*s.* 3¼*d.*) of Indian railways was :—

	£	
Standard gauge, 5 ft. 6 ins.	10,095	average cost per mile.
Metre gauge, 3 ft. 3⅜ ins.	4,519	„ „
Special gauges, 2 ft. 6 ins. and 2 ft.	2,093	„ „

London Railway Stations.

Particulars.	Cannon Street, London, South-Eastern Railway.		Charing Cross, London, South-Eastern Railway.	
	Total.	Per F.S.	Total.	Per F.S.

Charing Cross Station roof has since been rebuilt with a different type (1906).

LIGHT RAILWAYS.

Narrow-gauge Railways.—Approximate cost, including works and rolling stock, cuttings and embankments 2 ft. deep, and ballast 6 ins. to 14 ins. deep, but excluding cost of land.

Gauge.	Weight of Engines exclusive of Tender.	Max. Load per Wheel.	Weight per Yard of each Rail.	Cost per Mile, Single Track.
Ft. Ins.	Tons.	Tons.	Lbs.	£ £
2 0	6	1	20	1,500 to 2,000
2 6	9	1½	25	2,500 „ 3,000
3 0	12	2	30	3,000 „ 3,500
3 3½	17	3	40	3,500 „ 4,500
3 6	20	3½	50	4,000 „ 5,000

BELGIUM.—Over 1,000 miles of minor lines have been constructed at a cost, including rolling stock and all outlay, of rather less than 3,000*l.* a mile. These are generally on the metre gauge (3 ft. 3⅜ ins.), and as many of them appear to be laid on the roads the cost of land is very small. They earn about 6*l.* per mile per week, and working expenses are 66 per cent., or 4*l.* per mile per week. Net earnings of 2*l.* per mile per week give a return for over 3 per cent. per annum on the capital.

ENGLAND.—In England a line on the standard gauge, with no heavy work, would cost twice as much as the Belgian metre gauge railways, or say 6,000*l.* per mile. As regards land, a light railway can seldom do with less than an average width of 1 chain (66 ft.) or 8 acres per mile, and this at 100*l.* per acre comes to 800*l.* per mile. Hence to run the line on a strip of green alongside a road would save a good deal of expense, but this might involve bad gradients and sharp curves and the maximum speed would be reduced. The following are some actual costs :—

Clogher Valley Railway, Ireland (1885–87).—Length 37 miles, 3 ft. gauge, 45-lb. rail, and runs for the most part on the side of the road. Cost, 3,300*l.* per mile. It earns about 4*l.* per mile per week, but this is mostly absorbed in working expenses.

Listowel and Ballybunion Railway, Ireland (1888).—Length 9 miles, mono-rail supported on steel trestles, fastened to steel sleepers resting on wooden sleepers, with gradients up to 1 in 45, and worked by locomotives. Cost, including rolling stock, 3,666*l.* per mile.

Wisbech and Upwell Light Railway, Cambridgeshire.—Length 5¾ miles, with 2 miles of sidings, standard gauge, 50-lb. rail, and runs mostly on the edge of the road. Cost, excluding sidings, 7,000*l.* per mile of line. The earnings are about 9*l.*, and the expenses 7*l.* per mile per week.

Agrails.—The Decauville tracks of the new light railways, or 'agrails' as they are called, did admirable service at the front, both in France and Belgium. They were laid at a cost of 2,500*l.* per mile, and are now being put forward as a rival or as an adjunct to motor lorry traffic, to save the costly wear and tear of roads and to relieve congestion. They can be run on the edge of existing roads, with sidings on the various farms, but are only suitable for comparatively flat districts. The old narrow-gauge railways were too solidly and expensively built, but the agrails are of very light construction and should prove most useful.

RIVER CANALISATION, see Section XXIX.

RIVER REGULATION, see Section XXIX.

Excavating over areas in ordinary loose ground not exceeding 5 ft. deep, throw up, and form bottom to required levels or slopes	per y.c.	2	0
Spreading and levelling in layers not exceeding 12 ins. thick	,,	0	4
Add for well ramming, including watering as required	,,	0	5
Filling barrows and removing spoil not exceeding 50 yds., and depositing not exceeding 5 ft. high above starting-point	,,	1	3
Add for each 25 yds. beyond 50 yds., and up to 100 yds. total	,,	0	5
Removing over 100 yds., but not exceeding ¼ mile, and depositing	,,	2	8
Filling into carts or lorries, removing not exc. 1 mile, and depositing	,,	5	0
Surface digging in ordinary loose soil not exceeding 6 ins. deep, throwing into heaps, and forming bottom to camber or slopes	per y.s.	0	7
Ditto, ditto, 6–12 ins. deep, and ditto	,,	0	10
Levelling and ramming common earth for pavings, etc.	,,	0	2
Ditto, ditto, to camber or falls	,,	0	3
4 in. Hard core, or dry filling of clean broken brick, mason's spalls, etc., spread, levelled, and rammed to a true surface	,,	1	2
6 in. ditto, ditto	,,	1	9
9 in. ditto, ditto	,,	2	8
12 in. ditto, ditto	,,	3	6
4 in. Portland cement concrete, 1 to 6, of clean pit gravel or fresh-water ballast, spread and levelled, with spade-finished surface	,,	4	0
6 in. ditto, ditto	,,	6	0
9 in. ditto, ditto	,,	9	0
12 in. ditto, ditto	,,	12	0
Face of concrete worked up to an even surface to receive granite setts, wood blocks, asphalt, etc., including any additional cement	,,	0	10
Floating with wooden hand-float, or steel trowelling, to a fair and even surface, including additional cement	,,	1	3
¾ in. floated or trowelled surface, 1 to 2, as a screed or bed	,,	2	0

* For Cost of Road Maintenance, see 'HIGHWAY ENGINEERING,' Section XV.

Water-bound Macadam Roads.

The operations include materials, labour, steam rolling to finished thickness as below, and forming to slopes or camber, complete. Digging taken under 'Formation Surface and Foundations' in last section. 'Sub-base,' or 'sub-grade,' means the lower portion; 'bottoming,' or 'pitching,' the heavy stone foundation; 'crust,' the upper section; and 'carpeting,' the surface or wearing layer.

Cost of Measured Work—

		s.	d.
3 in. Furnace ashes, or ¾ in. gauge hard clinker bed, well rolled with a 10-ton roller	per y.s.	0	9
4 in. ditto, ditto	„	1	0
6 in. ditto, ditto	„	1	6
6 in. Bottoming or foundation of hard rubble stone, hand-packed, upper interstices filled with spalls, formed to camber, and rolled with a 2-ton roller	per y.s.	2	6
9 in. ditto, ditto, and rolled with an 8-ton roller	„	3	9
12 in. ditto, ditto, and rolled with a 10-ton roller	„	5	0
3 in. Gravel, good binding, in two thicknesses, 2 in. lower layer coarse screened to 1½ in. gauge, and 1 in. upper layer fine screened to ¾ in. gauge, well rolled with an 8-ton roller	„	2	6
4 in. ditto, but 3 in. lower layer, and 1 in. upper layer, ditto	„	3	0
3 in. Macadam surface of 2 in. broken granite, rolled once dry with a 10-ton power roller, then well rolled whilst being watered by a water-cart having a rose spray pipe, and a surface binding of fine chippings, ⅛–¾ in. gauge, of the same material, to fill the interstices during subsequent rolling, until the whole is thoroughly consolidated (sand and road sweepings prohibited)	„	5	6
4 in. ditto, ditto	„	7	0
6 in. ditto, ditto	„	10	0

3 in. whinstone,	4*s.* 0*d.* per y.s.		3 in. hard limestone,	3*s.* 9*d.* per y.s.

Steam or power rolling with a 6- to 8-ton roller (including driver, attendance, fuel, water, oil, depreciation of machinery, etc.), gravel 3–4 in. thick, and 500–1,000 y.s. area, within a radius of one furlong	„	0	3
Ditto, ditto, but exceeding 1,000 y.s.	„	0	2
Ditto, with a 10-ton roller for macadam 3–4 in. thick, and 500–1,000 y.s. area, within a radius of one furlong	„	0	4
Ditto, ditto, but exceeding 1,000 y.s.	„	0	3
Hire of steam or power roller, including driver, fuel, water, oil, depreciation of machinery, etc., per working day	50*s.* to 60*s.*		
Ditto, ditto, per day standing by	20*s.* „ 25*s.*		
Watering roads, including horse, driver, van, and water, per 1,000 y.s.	5*d.* „ 9*d.*		
Ditto, ditto, but exclusive of water	2*d.* „ 4*d.*		

Complete Estimated Costs of Water-bound Macadam Roads, based on the foregoing, for three ordinary types, carriage-way only, and exclusive of drains, channels, kerbs, and footpaths. For cost of these to add see later section on 'Footpaths,' which vary in width and materials.

	Approximate. Per y.s. *s.*	Per Mile. £
By-Roads for light traffic, 20 ft. wide, including digging in ordinary ground, forming bottom to camber, removing spoil ¼ mile and depositing, 3-in. bed of furnace ashes, 6 in. bottoming of hard rubble stone, 3 in. whinstone metalling, 2 in. gauge, and a surface binding of fine whinstone chippings, ⅛–¾ in. gauge, watered and rolled, 12 in. total thickness	9	5,300
Ordinary Roads, or highways for moderate traffic, 30 ft. wide, digging, etc., as before, but 4 in. bed of ashes, 9 in. stone bottoming, 4 in. whinstone metalling, and surface chippings, 17 in. total thickness	12	10,600
Main Roads for heavy traffic, 40 ft. wide, digging, etc., as before, but 6 in. bed of ashes, 12 in. stone bottoming, 6 in. whinstone metalling, and surface chippings, 24 in. total thickness	17	20,000

Tar Macadam Roads.

Tar is used on roads for—Tar macadam (surface layer); grouted macadam (surfacing by penetration method); tar spraying (hot surface dressing); and tar emulsions (cold surface dressing and patching). *Rocmac*, *Tarmac*, *Tarvia*, etc., are proprietary articles. Digging, bed, bottoming, etc., will be found under previous sections.

Cost of Measured Work—

		s.	d.
3 in. Tar macadam of hard limestone, basalt, etc., in two layers: the lower of two parts of 2 in. gauge tarred stone as a sub-crust, and one part of 1½ in. gauge as a wearing surface, well rolled with a 10-ton power roller. During the subsequent rolling apply an upper or 1 in. binding layer of tarred stone, ¼–¾ in. gauge (equal in bulk to 10–15 per cent. of main layer), well rolled in to properly fill the interstices. Heat the coal-tar to about 270° F. before mixing with the perfectly dried and heated stone, allowing 9–12 gals. per cu. yd. of stone, and to comply with the Ministry of Transport Specification No. 3 (*b*) for Standard Tar No. 2. (After one to two months' traffic the surface to be tar sprayed and blinded as a sealing coat, separate payment for this being made)	per y.s.	6	0
4 in. ditto, ditto	,,	7	6
5 in. ditto, ditto	,,	9	0

If blast-furnace slag is used instead of limestone deduct—

3*d.* for 3 in. thick; 4*d.* for 4 in.; 5*d.* for 5 in., per y.s.

Tar spraying first time (1 gal. to 5–7 y.s.) with No. 1 standard dehydrated coal-tar under pressure, heated on the spot to about 270° F., including preliminary sweeping and afterwards blinding with ¼ in. fine pea gravel, or limestone or granite chippings, free from dust, and not mixed with tar, and light rolling .	,,	0	6
Ditto, if sprayed previously (1 gal. to 8–10 y.s.), ditto, ditto	,,	0	5
Resurfacing macadam in repairs by roughing and sweeping surfaces of tar or ordinary macadam, applying one coat of No. 2 Standard Tar, heated to boiling point on the spot, and whilst surface is hot rolling in tar macadam, ¼–¾ in. gauge, averaging 1 in. thick. Finished surface to be then tar sprayed (1 gal. to 5–7 y.s.), and blinded with fine limestone siftings during rolling	,,	3	6
itto in 'pot-holes' and small patches, 5–25 y.s. in the aggregate at one time .	,,	4	0

Complete Estimated Costs of Tar Macadam Roads, based on the foregoing, for three ordinary types, carriage-way only, and exclusive of drains, channels, kerbs, and footpaths. For cost of these to add see later section on 'Footpaths,' which vary in width and materials.

	Approximate. Per y.s.	Per Mile.
	s.	£
By-Roads for light traffic, 20 ft. wide, including digging in ordinary ground, forming bottom to camber, removing spoil ½ mile and depositing, 3 in. bed of furnace ashes, 6 in. bottoming of hard rubble stone, 3 in. tar macadam of hard limestone, and an upper or binding layer of tarred stone, ¼–¾ in. gauge, to fill the interstices, all well rolled, 12 in. total thickness (including tar spraying and blinding after one to two months' traffic) . . .	11	6,400
Ordinary Roads, or highways for moderate traffic, 30 ft. wide, digging, etc., as before, but 4 in. bed of ashes, 9 in. stone bottoming, 4 in. tar macadam, and binding layer of small tarred stone, 17 in. total thickness (including tar spraying and blinding after one to two months' traffic) . . .	14	12,300
Main Roads for heavy traffic, 40 ft. wide, digging, etc., as before, but 6 in. bed of ashes, 12 in. stone bottoming, 5 in. tar macadam, and binding layer of small tarred stone, 23 in. total thickness (including tar spraying and blinding after one to two months' traffic)	19	22,300

Reinforced Concrete Roads.

Reinforced concrete should be—6 in. thick for residential areas and light traffic.
7 ,, ,, ordinary roads and streets.
9 ,, ,, main roads heavily trafficked.
12 ,, ,, very heavy city traffic.

Digging, bed, bottoming, etc., will be found under previous sections.

Two-course concrete, 6 in. total combined thickness, including preparing, wetting, and rolling formation surface to proper gradient and cross-section with a light 2- to 5-ton roller, placing a 4½ in. under layer of British Portland cement concrete, 1 : 2 : 4, of 1½ in. gauge limestone, reinforced 1½ in. from bottom surface with No. 9 B.R.C. steel fabric (4·71 lbs. per y.s., and having 2 in. side lap and 12 in. end lap) and a 1½ in. upper layer of hard-wearing fine granitic concrete, 1 : 1½ : 3, of ½ in. gauge granite chippings, screened free from dust. Each concrete layer to be well tamped, and the upper to follow the lower as rapidly as possible, and in *no* case more than 20 minutes later, before the latter has had time to set, so that the two may firmly unite as one mass. The final top surface to be screeded off and finished with a canvas band to remove excess moisture, then covered with 2 in. of sand or loam kept well wetted for 21 days till the concrete

	s.	d.
is cured and properly set. (Ordinary Portland cement hardens in 7 days, Ferrocrete in 3 days, and Ciment Fondu in 1 day.) Camber, 1 in 40 to 1 in 50 . per y.s.	12	6
Add for each additional inch of concrete in 1 : 2 : 4 under layer, with 1½ in. gauge limestone (up to 9 in. combined thickness) . . . . . ,,	1	3
Solution of Brunner Mond's P. 84 silicate of soda, sprayed and brushed in 3 separate coats, for hardening and dust-proofing the surface of concrete roads (1 gal. tin, 6s.), in the proportion of 1 gal. silicate to 4 gals. water . . . ,,	0	1½

Complete Estimated Costs of Reinforced Concrete Roads, based on the foregoing, carriage-way only, and exclusive of drains, kerbs, and footpaths. For cost of these to add see later section on 'Footpaths,' which vary in width and materials. The carriage-way should be extended 12–18 in. under the kerbs.

	Approximate. Per y.s. s.	Per Mile. £
By-Roads for light traffic, 20 ft. wide, including digging in ordinary ground, forming bottom to camber, removing spoil ¼ mile and depositing, 3 in. bed of furnace ashes or clinker and rolled (if the formation surface is clay), and 6 in. total thickness of reinforced concrete (4½ in. lower layer, 1 : 2 : 4, of 1½ in. gauge limestone, and 1½ in. upper layer, 1 : 1½ : 3, of ½ in. gauge granite chippings—sometimes 4 in. lower, and 2 in. upper) . . .	15	8,800
Ordinary Roads, or highways for moderate traffic, 30 ft. wide, digging, etc., as before, but 4 in. bed, and 7 in. total thickness of reinforced concrete (5 in. lower, and 2 in. upper)	17	15,000
Main Roads for heavy traffic, 40 ft. wide, digging, etc., as before, but 6 in. bed, and 8 in. total thickness of reinforced concrete (6 in. lower, and 2 in. upper)	19	22,300
Arterial Roads have 8–9 in. reinforced concrete carriage-ways 30–70 ft. wide, on 4–12 in. bed of clinker, hard core, or furnace ashes, with grass margins, and footways 10–15 ft. wide, or 100–120 ft. total width between fences (for very heavy traffic double reinforcement is sometimes used, weighty steel at bottom and light at top, 5–7 lbs. per y.s., and 2 lbs. per y.s.), per mile	£ 50,000	£ to 100,000

Actual Costs of Reinforced Concrete Roads.—The Greater London Arterial Road Scheme (1920–27) comprises new wide reinforced concrete by-pass roads surrounding London, to enable traffic to go round the city and avoid congesting busy areas. These include the North Circular Road, the South Circular Road, the Eastern Avenue, the Western Avenue, the Great West Road, the Great Cambridge Road, and others. Some stretches may be seen at Edmonton, Enfield, Southwark, and Willesden. They are 100–120 ft. wide between fences, but a carriage-way about 24 ft. wide is only done first, the remainder as funds permit. Other towns are constructing similar great highways.

North Circular Road (1922–23).—Planned to form a complete circuit from Kew Bridge over the Thames on the south, passing round London at a radius of 6½ miles from Charing Cross into Essex at Walthamstow, and from thence to the Thames Ferry at Woolwich, and also connecting with the roads to the Eastern Counties. Length about 17 miles, of which 6 miles are existing roads widened and reconstructed, and 11 miles of new road, including bridges over 12 railways and many streams. New road built in three lengths, 100 ft. wide, with two 24 ft. reinforced concrete carriage-ways, 20 ft. in the middle for tramways, and two 16 ft. footpaths. Construction varied, but at Willesden it was 4–6 in. clinker bed, 5 in. lower course of concrete, 1 : 2 : 4 and 1 : 2½ : 5, of 2 in. gauge ballast graded down to ⅜ in., reinforced with B.R.C. or Walker-Weston reinforcement, 12 lbs. per y.s., placed 2 in. from surface, 3 in. top course of concrete, 1 : 1 : 3, of crushed river ballast, ⅜–$\frac{3}{4}$ in. gauge, deposited immediately to form one homogeneous mass of 8 in. total thickness. Concrete was machine-mixed, and no expansion joints, but only 40 ft. whole width lengths were laid at one time to avoid cracks. Camber 1 in 48, surface treatment tar and grit. 12 × 6 in. reinforced concrete kerbs, with carriage-way extended beneath. Direct labour. Cost, excluding excavation, 11*s.* 4*d.* to 12*s.* 10*d.* per y.s. Whole work, about 1,200,000*l.*, or 71,000*l.* per mile.

Western Avenue (1922–23).—Leaves London at Shepherd's Bush, passes through Acton and Greenford, and rejoins the present Oxford Road in Bucks at Denham. It has 5 bridges over railways, one over the river Brent, and one over an industrial siding. Length 12 miles, with two 24 ft. carriage-ways and an intervening 20 ft. space for future developments, but only one carriage-way was made first. From Acton to Greenford 30 ft. central carriage-way, tar-painted gravel footways, and grass margins with trees. Subsoil very wet clay throughout the whole length; little cutting or filling, except filling at approaches to bridges. Carriage-way of 8 in. reinforced concrete, granitic faced, laid in alternate bays. On deep fills hard core, and tar macadam surfacing. Footways generally of gravel tar-painted, with 12 × 6 in. granite kerbs. Surface-water drains in one margin only, with cross drains connecting to gullies on both sides of carriage-way. Estimate for Middlesex section of 12 miles was 666,000*l.*, or 55,500*l.* per mile. 4½ miles cost 285,000*l.*, or 60,000*l.* per mile.

Great West Road (1919–24).—In Middlesex, from Chiswick High Road to the main Bath and West of England Road, near Hounslow Heath. Length 8½ miles, but only 5½ miles done up to 1924. Total width between fences 120 ft., the carriage-way at first only 50 ft. (but capable of being widened to 80 ft.), with two grass margins 25 ft. wide, trees 60 ft. apart, and two 10-ft. footways. Parts of grass strip available for future widening of footways. Subsoil generally of brick earth overlying sandy gravel. Foundation of 12 in. hard core and ashes, overlaid with 9 in. reinforced concrete, 6 in. lower course, 1 : 2½ : 5 of washed gravel, 1½ in. gauge graded down to ⅝ in., with B.R.C. fabric 2 in. from bottom, and 3 in. upper course, covered with 2 in. rock asphalt treated with bituminous dressing and granite chips. Footpaths of gravel, tar-painted, but slab paving in built-up areas, with 12 × 8 in. granite kerbing laid on the extended sides of the reinforced concrete road-bed, and concrete channels. The work included 4 new bridges, 80 ft. wide, one bridge widening, sewers and surface water drains on both sides, subways for cross mains, one subway being 33 ft. wide to take one 42 in. and two 66 in. mains, costing 11,730*l.*, the deepest cut being 18 ft. and the heaviest fills 17 ft., demolition of 60 houses and building new ones instead, etc. Concrete laid in alternate bays with butt joints, part having expansion joints. Gross expenditure 834,482*l.*, of which construction costs, including duplicate sewers and surface water drains, represented 670,152*l.*, or 130,760*l.* per mile.

Great West Road Extension (1922–23).—Links up the Brentford By-pass with the Basingstoke Road. Length, 3 miles. Highway 100 ft. wide, and 30 ft. central carriage-way with grass margins, trees 60 ft. apart, and two gravel footways tar-painted, with 12 × 6 in. granite kerb. Subsoil mainly gravel and old pits filled up. 6 in. clinker bed well rolled, 8 in. concrete carriage-way, 1 : 2 : 4, aggregate of washed pit ballast, 2 in. gauge down to ½ in., and some of ¾ in. shingle, machine-mixed, and reinforced with steel fabric. Surface partly asphalt carpet, and partly tarred. Half a mile laid without expansion joints, the remainder in alternate bays. Surface-water drains on both sides. Work included a ferro-concrete bridge, 60 ft. wide and 30 ft. span, and two smaller ones. Total, 124,000*l.*, or 41,330*l.* per mile.

Great Cambridge Road (1921–23).—An entirely new road from near Finsbury Park running through Tottenham, Edmonton, and Enfield to join the Hertford Road at Wormley. Length, 7 miles. Total width between fences 100 ft., with one prepared carriage-way 24 ft., but actually planned for two with an intervening space of 20 ft. for future tramways, etc., and trees planted 60 ft. apart. Two 6-ft. footpaths on either side adjoining the boundaries, gravelled and tar-painted, with 12 × 8 in. and 12 × 6 in. concrete and granite kerbs. Subsoil mostly brick earth overlying gravel, and southern mile of very bad clay. An old gravel pit, 30 ft. deep, on line of road, was filled up. 3–6 in. clinker bed, 8 in. reinforced concrete carriage-way, 1 : 2 : 4, of ballast and shingle, 2 in. gauge graded down to ¼ in., and cambered 1 in 48. Surface-water drains on both sides. Scheme comprised three ferro-concrete bridges over rivers, and over a railway. Total, 330,000*l.*, or 47,140*l.* per mile. First sections cost 13*s.* per y.s., but later sections only 10*s.* 6*d.* per y.s. (June 1922). A continuation of 3¼ miles by contract came to 12*s.* 4*d.* per y.s., excluding excavation (August 1923).

Central Drive, Westhoughton, Lancashire (1922).—120 yds. long and 25 ft. wide. Foundation of 4 in. furnace ashes rolled. Concrete in two courses—4 in. lower, 1 : 2 : 4 local stone, with fabric reinforcement 2 in. from bottom, and 2 in. upper, 1 : 1½ : 3 granite chippings, with tamped surface finish. Camber, 1 in 40. No expansion joints, concrete cured with damp sand, allowing three weeks to set. Cost, 12*s.* 9*d.* per y.s.

Ipswich Housing Estate (1922).—Total length of roads, 1,890 yds.; average width between kerbs, 21 ft. Concrete in two courses, totalling 5–6½ in. Lower course, 1 : 2 : 4 sea shingle, reinforced 1 in. from bottom, and upper course, 1 : 2 : 2 granite chips, rammed to form a granolithic surface finish. Camber, ¼–1 in. No expansion joints, concrete cured with wet sand. Direct labour. Cost, 13*s.* 4*d.* per y.s.

South Cliff, Hartlepool (1922).—New concrete road 200 yds. long and 24 ft. wide between kerbs, in one 6 in. course only. Excavation steam rolled and properly shaped, with bed of fine destructor ashes to receive the concrete, 1 : 1⅓ : 3½ slag, reinforced 2 in. from bottom, and machine-mixed. Work done in full widths, surface finished with screed or straight edge. Camber, 1 in 40. No cross expansion joints, but a longitudinal expansion joint of 1½ in. fine tarred slag alongside each kerb. Direct labour. Cost, 10*s.* per y.s.

Streets in Sheffield (1922).—31 streets reconstructed in 6-in. concrete from existing macadam. Combined length, 3,411 yds.; average width between kerbs, 19 ft. Two courses: 5 in. bottom, 1 : 5 broken gritstone, and 1 in. top, 1 : 2½, surface tamped. No reinforcement except over trenches. Concrete machine-mixed, and work in whole widths. Crossfall, 3 in. No expansion joints, and 7 days before traffic allowed. Direct labour. Cost, 16*s.* 6*d.* per y.s.

Streets in Southwark (1922–23).—Original granite macadam roadway excavated 9 in. deep, and rolled to receive 6 in. two-course concrete—4 in. lower, 1 : 6, with ⅜ in. interlaced rod reinforcement 2 in. from bottom, and 2 in. upper, 1 : 3, laid quickly before the lower course had time to set. Aggregate was the material from the old macadam road. Concrete cured with 2 in. damp sand kept wet at least 10 days, and no traffic allowed for three weeks. Surface lightly treated with tar or silicate of soda. Cost, including excavating, watching, materials, and labour, 10*s.* to 14*s.* 6*d.* per y.s.

Sett Paving.

Sometimes called pitcher paving. Digging, and concrete or rubble stone foundation, will be found under previous sections.

		s.	d.
4 × 4 × 5 in. deep, squared and hammer-dressed granite paving cube setts, joints squared 3 in. back from faces, bedded in screened gravel or hard screened clinker, and grouted flush with cement mortar, 1 to 3 (exclusive of digging and foundation)	per y.s.	24	0
8–9 in. long × 3 in. wide × 5 in. deep, ditto, ditto	„	26	0
Add or deduct for each inch of greater or less depth	„	4	0
Deduct if grouted in pitch mixture instead of cement mortar	„	0	3
Add if sett paving is laid in straight gutters or channels separate or detached from other paving	„		
Add if sett paving is laid over concrete foundation (excluding same), including bedding in cement mortar, 1 to 3, and grouting flush	„		
Taking up setts 5 in. deep, cleaning, and relaying, including gravel bed and grouting flush with cement mortar, 1 to 3	„	5	0
Complete Estimated Cost, based on foregoing, for 4 × 4 × 5 in. granite setts, grouted and bedded in cement mortar, 1 to 3, on and including 9 in. concrete foundation, floating to an even surface, and digging in ordinary soil	„	36	0
8–9 in. × 3 in. × 5 in. granite setts, ditto, ditto	„	38	0

Wood Block Paving.

Digging and concrete foundation will be found under previous sections.

		s.	d.
Wood block paving of selected Baltic fir or yellow deal, 9 × 3 × 4 in. deep, creosoted in vacuum with 8–10 lbs. creosote oil per cu. ft. of timber, the lower ends of blocks dipped in pitch mixture whilst being laid close together end grain up, then grouted by squeegee with the same mixture, a $\frac{1}{16}$ in. layer being left on the top surface and blinded with fine pea gravel. Mixture is 1 cwt. coal-tar pitch, as described in British Standard Specification No. 76, slightly thinned with 1 gal. creosote oil and heated to 300° F., but cooled to 270° F. at time of dipping and grouting. Cross fall, 1 in 40. (Price is exclusive of digging and concrete foundation)	per y.s.	14	0
Ditto, 9 × 3 × 5 in. deep, ditto, ditto	„	16	0
Taking up old wood blocks, 3–5 in. deep, removing 20 yds. and stacking	„	0	9
Ditto, including cleaning and trimming for relaying	„	1	6
Puddled clay expansion joints, 1 in. wide, at edge of road	per f.r.	0	1½
Pitch and tar ditto, ¾ in. wide	„	0	2
Cutting and waste to splays and rounded angles	„	0	6
Cutting only to wood blocks	„	0	2
Complete Estimated Cost, based on foregoing, for 9 × 3 × 4 in. wood blocks, dipped and grouted with pitch mixture, and surface blinded with fine gravel, including 9 in. concrete foundation, floating to a fair surface, and digging in ordinary soil	per y.s.	25	0
9 × 3 × 5 in. deep, ditto ditto	„	27	0

Asphalt.

1–1½ in. thick for pavements and footpaths; 1½–2 in. for roads and carriage-ways. Prices laid in London, by the Asphalt Company's own workmen. Digging and concrete foundation will be found under previous sections.

		s.	d.
1 in. Asphalt paving in two ½-in. layers, quantities not less than 100 y.s.	per y.s.	7	6
1½ in. ditto, in 1 in. and ½ in. layers, ditto	„	10	3
2 in. ditto, in 1 in. and 1 in. layers, ditto	„	12	9
Taking up old asphalt, any thickness, and removing	„	0	8
Labour only in forming channels and gutters, 6–9 in. girth	per f.r.	0	7
Complete Estimated Cost, based on foregoing, for 1 in. asphalt on footpaths, including 3 in. concrete foundation, floating to a fair surface, and digging in ordinary soil	per y.s.	12	0
2 in. Asphalt on roads, including 9 in. concrete foundation, floating, and digging	„	24	0

Footpaths.

The following prices are exclusive of digging or foundations, which latter may be of 3–4 in. furnace ashes, clinker, rubble stone bottoming, hard core, concrete, etc., according to the support required by the paving material; see previous sections.

		s.	d.
2 in. Gravel, good binding, coarse screened, with ¾ in. fine screened gravel on top, rolled down to a finished thickness with a 30-cwt. roller	per y.s.	2	0
3 in. ditto, in two layers: 2 in. coarse and 1 in. fine, rolled with 2-ton roller	„	2	4
2 in. Tar paving in one main layer of 1½ in. gauge tarred limestone, rolled with a 2-ton roller, then a binding coat of ¼–¾ in. tarred stone to fill the interstices, after which final rolling with a 30-cwt. roller	„	4	6
3 in. ditto in two layers: the lower 2 in. of 1½ in. gauge tarred stone well rolled before the upper 1 in. of ¼–3 in. tarred stone is applied and also rolled. Finished surface is then tar sprayed under pressure (1 gal. to 5–6 y.s.), and blinded with fine limestone siftings during final rolling	„	6	0

If blast-furnace slag is used instead of limestone deduct—

2*d.* for 2 in. thick; 3*d.* for 3 in. thick, per y.s.

		s.	d.
Vitrified blue Staffordshire pressed paving bricks, scored diagonally on face, 10 × 5 × 1½ in. thick, laid flat and straight on 1 in. layer of sand, or furnace clinker screened to ½-in. mesh, and grouted with cement	„	9	0
Ditto, ditto, laid and jointed in cement mortar	„	10	6
1 in. Stuart's granolithic paving laid in London area.	„	4	0
2 in. ditto, ditto	„	6	6
2 in. Yorkshire or Caithness smooth stone flagging, not less than 4 f.s. area each, edges squared and jointed, laid in lime mortar and jointed with cement mortar, 1 to 3, including forming the ground to required levels and removing surplus earth	„	19	6
2½ in. ditto, ditto	„	23	0
3 in. ditto, ditto	„	26	6
2 in. Pre-cast granitic concrete flagging, 1 cement to 3 granite chippings and fine stuff, laid as last	„	13	0
2½ in. ditto, ditto	„	15	6
Add to last five items if laid in cement mortar instead of lime mortar	„	0	6
1 in. Granitic surface, 1 cement to 2 granite chippings, incorporated whilst concrete is unset, and trowelled to a smooth face	„	4	0
Spike rolling, or flute rolling, surfaces of new concrete	„	0	4

Channel stones, not less than 3 ft. long, finely quarry scabbled upon upper surface, and on side and end joints 3 in. from face, including setting complete in lime mortar:

Size of Channel Stones.	Granite.	Whinstone.	Limestone.	Pre-cast Granitic Concrete, 1 : 2 : 4.	
	s. d.	s. d.	s. d.	s. d.	
10 × 4 in. section, per ft. run	4 0	3 4	3 2	2 2	
12 × 5 in. „ „	5 6	4 8	4 2	2 9	s. d.
Add to any of foregoing if set and jointed in cement mortar instead of lime mortar					per f.r. 0 1

Kerb stones for footpaths, not less than 3 ft. long, finely quarry scabbled on top, 6 in. one side, and on end joints and remaining side joint for 3 in. from face, including setting complete in lime mortar:

Size of Kerb Stones.	Granite.	Whinstone.	Limestone.	Pre-cast Granitic Concrete, 1 : 2 : 4.	
	s. d.	s. d.	s. d.	s. d.	
5 × 10 in. edge, per ft. run	4 6	3 8	3 5	2 4	
6 × 12 in. „ „	6 0	4 10	4 4	3 2	
10 × 6 in. flat „	5 6	4 6	4 3	2 10	
12 × 6 in. „ „	6 6	5 4	4 9	3 3	s. d.
Add to any of foregoing if set and jointed in cement mortar instead of lime mortar					per f.r. 0 1

(See also 'Highway Engineering,' Section XV.)

Roofs.

	£	£	
Roofs, light, corrugated iron, 18 to 22 gauge, exclusive of iron or steel trusses		2 to 3	per square.
Roofs for light cheap sheds and buildings, including trusses, corrugated sheeting, gutters, etc., fixed complete		5 ,, 8	,,
Roofs, ordinary steel and iron, including purlins, boarding, gutters, etc.		5 ,, 10	,,
Roofs, railway station platform, with glass		10 ,, 20	,,
,, ,, termini, over 150 ft. span, fixed complete		30 ,, 45	,,
Roof trusses, delivered only, for galv. iron		4*s.*	per foot of span.
,, ,, ,, for slates		8*s.*	,, ,,

Railway Station Roofs.

Railway and Station. (Old titles of Railways.)	Span of Roof.	Covered Area.	Cost per Square of 100 F. S.	Additional for one Gable.
	Feet.	Sq. Yds.	£ *s.* *d.*	£ *s.* *d.*
London, Brighton and South Coast Railway, Victoria Station (1860)	120	—	27 13 4	with gable
London & North-Western Railway, New Lime Street Station	212	—	30 0 0	—
Midland Railway, St. Pancras Station (1868)	240	18,822	31 11 0	4 7 0
South-Eastern Railway, Cannon Street Station (1867)	190	13,875	43 10 0	6 0 0
South-Eastern Raily., Charing Cross Station (1864)	166	8,888	34 0 0	6 0 0

Victoria Station and Charing Cross Station have since been entirely rebuilt.

Sea Cables.

The cost of a light submarine cable laid on the ocean bed is 200*l.* to 400*l.* per nautical mile laid (1928). Heavy trunk lines, 400*l.* to 800*l.* ditto. One nautical mile = 2,027 yds.

Seaside Resorts.

Based on actual costs, 1927.

Bathing Pools, open, including accommodation for spectators, require a capital outlay of about 1*l.* per head of population, or 20*l.* to 30*l.* per square foot of water area.

Bathing châlets, with gas and water laid on, frequently fetch a rental of 35*l.* to 50*l.* a year.

Foreshore Lay-out is commonly 2*l.* per head of population, and in one case was 17*l.* per head.

Groyning, to form and maintain beaches, may cost 15,000*l.* per mile of beach.

Hard Tennis Courts, red or green, 6*s.* to 7*s.* per square yard of surface.

Sea-Walls.

Sea-walls to protect coast line, formed of 1 to 6 Portland cement concrete, 10 ft. high from base to top, 4 ft. average thickness, including foundations and excavating in clay, in tide-work, pre-war average cost—

6*l.* per yd. run, or 2*l.* per ft. run.

Pre-war actual costs from *Marine Works*, by E. Latham, M.I.C.E. (1922. 16*s.* Crosby Lockwood & Son, London.)

	Cost per yd. run. £ *s.* *d.*
Bridlington.—Alexandra sea-walls (1879). 340 yards long, of mass concrete 5 ft. thick at base and 3 ft. at top, curved on face. Concrete apron, 9 ft. wide, and 2 to 2½ ft. thick, the toe-piece being 6 ft. deep and 18 ins. thick. Back of wall is battered 1½ in. per foot. Counterforts at 20 ft. centres. Wall is 20 ft. high, with projecting cornice, coping, and handrail. Chains embedded to act as bonds for the concrete. For details see *Coast Erosion and Protection*, pp. 49–50, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London); and *Proceedings of the Institution of Civil Engineers*, vol. clix. p. 65. Total, £5,657	16 12 9
Bridlington.—Beconsfield sea-wall (1888). 340 yards long, with Bramley Fall rock-faced stone and concrete backing. 1¾ in. wrought-iron tie-rods at intervals. 12 ft. 3 ins. thick at base, and 4 ft. at top, stepped and curved on face. Total height, 25 ft. 7 ins., with projectng cornice, coping, and handrail. Counterforts, 3 ft. 6 ins. by 3 ft. 6 ins, and 20 ft. apart, centre to centre. For details see *Coast Erosion and Protection*, pp. 47-48, by E. R. Matthews, AM.I.C.E. (1918. Charles Griffin & Co., London.) Total, £10,000	29 8 3

Cost per yd. run.

	£ s. d.
Bridlington.—Sewerby sea-defence (1896). 305 yards long. Combination of rubble and timber, with two rows of 12 in. × 12 in. pitch-pine piles, 10 ft. apart. Front piles are 15 ft. long driven 9 ft. into the clay, and back piles 23 ft., driven 10 ft., with tie piece, 9 ins. × 4 ins. Face of 11 in. × 3 in. planking, and back planking 11 ins. × 4 ins., with 9 in. × 6 in. bearers and 11 in. × 4 in. ribs. Puddle clay backing, 2 ft. 6 ins. thick. Block chalk filling between the timber work. Foot-path on top. For details see *Coast Erosion and Protection*, pp. 86–88, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London); and *Proceedings of the Institution of Civil Engineers*, vol. clix. p. 65. Total, £3,000 . . .	9 16 8
Extension of ditto in 1899, by 82 yards, £788	9 12 2
Chatham (1913).—Reinforced concrete revetment on the De Muralt system on the banks of the Medway. Protects a length of 90 yds. of bank between two wharves	7 15 5
Frinton (1912–13).—Reinforced concrete apron 200 yds. long, to protect a stone pitched sea-wall at Frinton in Essex, which was being undermined by the waves. Apron 12 ft. wide, sloping 1 in 12, and 4 ins. thick, reinforced with Clinton fabric and ½ in. steel bars. Front toe wall, 9 ins. thick and 2 ft. high, with ½ in. steel bar reinforcement. 6 in. × 3 in. reinforced concrete ribs, with ½ in. steel bars .	2 5 0
Hornsea.—Reinforced concrete sea-wall. For details see *Proceedings of the Institution of Civil Engineers*, vol. cxxxv. p. 151	39 0 0
Lowestoft (1901–1903).—North Denes. Mass concrete sea-wall on steel piles, including steps, filling, and excavation. Total length with returns, 5,744 ft. run. Cost per yd. cube, 21*s.* 2*d.* For details see *Proceedings of the Institution of Civil Engineers*, vol. clxxxv. p. 106	5 11 6
Maintenance.—Maintenance of earthen embankments along river fronts or sea shores, about 18 ft. high to top of wall and protected by stone pitching or light reinforced concrete revetment; average cost of maintenance per annum (1910–13) when in normal repair	4*d.* to 4½*d.*

SEWAGE WORKS.

Sewage disposal works for cities and towns . . .	3*l.* to 6*l.* per inhabitant.
Bacteria filter-beds with earth embankments and floors, completed with clay puddle, and filled in with clinker or coke breeze 3 ft. deep	5*s.* to 10*s.* per yd. sup.
Ditto with concrete walls, and clinker or coke breeze 4 ft. deep	20*s.* to 30*s.* ,,

Precipitation and sludge tanks in the north-west of England, to treat a million gallons of sewage daily, built in 1910. From actual tenders received.

	£
Scheme with cast-iron tank plates	7,000
,, ,, brickwork in cement	6,000
,, ,, reinforced concrete	4,500

Bio-aëration System.—Complete works on the bio-aëration system, including aëration or circulating tanks, settling tanks of the Dortmund type, gauging chambers, sludge wells, motor houses, pump houses, etc., cost from 25,000*l.* to 30,000*l.* per million gallons, d.w.f., according to size and local circumstances (1924).

Activated Sludge Process.—The estimated cost for a complete activated sludge scheme, dealing with all storm water and treating all the sludge, is 1*l.* per head (1924).

Reading.—Activated sludge plant on the diffused air method, completed in 1924, designed to treat the whole flow of the city, amounting to 3½ million gallons d.w.f. per 24 hours, from an estimated future population of 120,000, cost 72,813*l.*, or 12*s.* 1½*d.* per head.

Strensall Camp Sewage Works, near York (1914–16).—For 1,000 nominal number of troops at 20 gals. per head per day, or 20,000 gals. sewage per day. Lift system, ground being low and sandy. Drainage connections comprised replacing 86 e.c.'s by w.c.'s, 18 additional w.c.'s, or 104 total w.c.'s, 234 gullies, and 80 manholes, with 4-in. and 6-in. stoneware drains gravitating to the ejectors. Brick engine shed, 15 ft. by 14 ft., for air compressor plant with 2 gas engines, and 4 ejector pits, with 12-in. concrete walls lined with ⅜-in. cast-iron plates, and concrete floors with expanded metal; pits octagonal in plan, 12 ft. internal diameter and 12 ft. average depth, containing 5 pneumatic ejectors, 25 gallons each, 1 pit holding 2 ejectors. 2½ in. steel compressed air mains from engine-house to ejectors, which raise sewage to the 5-in. and 6-in. cast-iron rising main drains and thence 1,700 yards (about a mile) to the outfall works. Total lift for sewage, 19 feet. Outfall works include two reinforced 6-in. concrete tanks, 20 ft. × 10 ft. × 6 ft. each, containing 7,500 gallons, or 15,000 gallons altogether; two brick sludge beds, 20 ft. × 10 ft. × 3 ft. each, with 10-in. screened ashes at bottom and 4-in. agricultural drains on 6-in. concrete floor; two circular filter beds, 46 ft. diameter, with rubble sides and reinforced concrete floors

filled with 5-ft. furnace clinker, ½-in. to 4-in. gauge, the liquid sewage being distributed by a revolving sprinkler delivering 84,000 gallons per day. Special filter tiles on floor for aeration, concrete surface channel all round, and effluent then taken by waterways for land irrigation prior to discharging into existing ditch. Cost under five separate contracts :—

	£
Drainage connections, w.c.'s, stoneware drains, and manholes	2,710
Brick engine shed, and four concrete and iron ejector pits	775
Five ejectors, compressors, two gas engines, 2½-in. steel air mains, and 5-in. and 6-in. cast-iron main drains	1,837
Outfall works, including tool house, wire fence, and entrance road	2,035
Preparation of 13 acres of land, waterways and ditches for effluent	493
Total cost	7,850

Cost per head, 7*l.* 17*s.*, or 392*l.* 10*s.* per 1,000 gals. per day treated.

Stands.

Permanent stands for athletic or race meetings, displays, processions, reviews, etc., constructed of brick, concrete, or reinforced concrete, with refreshment rooms, kitchens, offices, weighing and saddling rooms, lavatories, drainage, water supply, electric light, seats, etc., roofed or partly roofed—

2*l.* to 3*l.* per spectator, or head of accommodation.

Imperial Stadium, Wembley, near London (1920–1923).—Major axis, overall length, 900 ft. and maximum overall width 650 ft. Oblong of grass for football and sports in centre 492 ft. × 260 ft., with cinder running tracks, encircled by a wide stepped slope for spectators beyond which begins the structural work with terraces of concrete steps, roofed in for 650 ft. on each side of the stadium and provided with seats. Total accommodation, including seated grand stands, ring seats, standing enclosures and terraces, 125,200 spectators. A space of 16 ins. is allotted per ring seat, and 17½ ins. for a grand stand seat. Royal box, banqueting hall, 215 ft. × 70 ft., for 1,000 people, dressing-rooms, shower baths, lavatories, board-room, box office, gymnasium with seats for 250 spectators, recreation room with billiard tables and reading tables, buffets, cloak-rooms, tea-rooms for 600 people at a time, observation gallery, offices, press gallery, special heating, 96 turnstiles, telephones, electric lighting and cooking, wireless, good water supply and drainage, etc. The whole structure is of reinforced concrete on a steel skeleton, and there are 25,000 tons of concrete, 1,400 tons of structural steelwork, 31 terraces of concrete steps on steel joists, girders, and stanchions, and steel-framed roofs covered with corrugated asbestos sheets. Height from ground to roof eaves of stand is 50 ft. Two towers 160 ft. high, flank the royal entrance, and high walls on main frontage, with arched openings with an average span of 50 ft. The whole structure is larger than the Coliseum, Rome, which held 80,000 people. Architects, Sir John W. Simpson, F.R.I.B.A., and Mr. Maxwell Ayrton, F.R.I.B.A. Engineer, Sir Evan O. Williams, B.Sc., A.M.I.C.E. General contractors, Sir Robert McAlpine & Sons, and numerous sub-contractors. Total cost, 300,000*l.*, or 2*l.* 8*s.* per spectator.

Submarine Cables, see ' Sea Cables,' p. 2882.

Tanks.

Estimated Costs, 1930.

	Per Gal. of Capacity.	Per Cu. Ft. of Capacity.
	d. *d.*	*s.* *s.*
Underground concrete tanks, 5,000 to 10,000 gals, capacity, for storage of rainwater to barracks, laundries, mansions, public institutions, etc., complete with concrete bottom, walls, and roof, rendered in cement with smooth trowelled face, including digging in ordinary ground, clay, or gravel, and removing surplus soil	4 to 6	2 to 3
Cast-iron tanks above ground, rectangular or octagon, 5,000 to 10,000 gals. capacity, with cast-iron flanged plates bolted together to form bottom and sides, and painted, supported on brick or concrete base	5 to 7	2½ to 3½
Steel tanks, rectangular, 5,000 to 10,000 gals. capacity, with steel plates riveted together to form bottom and sides, painted, and fixed in position	6 to 8	3 to 4
Steel cylindrical tanks, circular on plan, 40,000 to 80,000 gals. capacity, comprising steel plates riveted together to form bottom, sides, and top, painted, and fixed in position	4 to 6	2 to 3

TELEPHONES.

Estimated Costs, 1930.

		£	£
Private telephones for indoor use in houses, offices, and public buildings, complete, including batteries, wire, staples, terminal instruments, etc.	each	20 to 25	
Add for every extra telephone connection, including indicator, switches, etc.	,,	8	,, 10
Overhead land wires, comprising one copper line weighing 150 lbs. per mile, with poles, stays, brackets, and insulators, but excluding terminal batteries and instruments, fixed complete	per mile	60	,, 70
Add for every additional wire and fixing	,,	25	,, 30
Extra for terminal batteries and instruments complete	per telephone line	20	,, 25
Construction of municipal telephone systems in large towns and cities, including all wires, poles, batteries, and instruments, complete,	per line or subscriber	40	,, 60

TRAMWAYS.

Approximate Cost per Mile (1930).	Single Track. £ £	Double Track. £ £
Electric tramways, overhead trolley system, with span wires, including buildings and equipment, but exclusive of generating station for electricity	15,000 to 25,000	30,000 to 40,000
Ditto, ditto, with side brackets or centre poles	15,000 ,, 20,000	28,000 ,, 36,000
Overhead equipment, including supports :—		
Span wire construction	2,500 ,, 3,000	3,000 ,, 4,000
Bracket arm construction	1,800 ,, 2,400	2,500 ,, 3,500
Permanent way, granite setts :—		
3 ft. 6 in. gauge, 100 lb. rails	8,000 ,, 10,000	15,000 ,, 18,000
4 ft. 8½ in. gauge, 100 lb. rails	10,000 ,, 12,000	17,000 ,, 20,000
Conduit system, centre slot, with underground wires, including special work	25,000 ,, 30,000	45,000 ,, 55,000
Cable tramways, mechanical, with underground cables, etc.	30,000 ,, 40,000	50,000 ,, 60,000
Horse tramways, with stables, cars, etc.	12,000 ,, 18,000	25,000 ,, 30,000
Steam tramways, with locomotives and cars	15,000 ,, 20,000	26,000 ,, 32,000

The cost of line per mile varies according to power station, plant, number of cars, cables, class of paving for permanent way, gauge and weight of tram-rails, car-sheds, etc.

PROPORTIONATE COST OF PARTS.

	Per cent.
Permanent-way construction	50
Overhead construction	10
Street alterations, etc.	5
Cables, feeder pillars, etc.	10
Power stations, buildings, plant, etc.	8
Tramcars	7
Supervision and incidental expenses	5
Compensation and legal charges	5
	100

Cars per mile of single line	3 to 6
Motor terminal voltage	500 to 550

Trolley vehicle system of electric railless traction (1930) :—	£ £
Capital cost per mile of route, double wire	4,000 to 6,000
Good overhead work, per mile	2,400 ,, 3,000
Vehicles, cost of each	1,500 ,, 2,000
Obtaining Parliamentary powers	2,000 ,, 5,000
Cost of working per car mile	1*s.* ,, 1*s.* 3*d.*
Traffic receipts per car mile	1*s.* ,, 1*s.* 8*d.*

ACTUAL COSTS OF TRAMWAYS PER MILE (PRE-WAR).

Parts of Construction.	Edinburgh Cable Conduit.	South London (1903). Electric Conduit.	Electrical Overhead Trolley System. Glasgow.	Huddersfield.	Leeds.	Sunderland
	£	£	£	£	£	£

Aberdeen, overhead trolley system, 4 ft. 8½ in. gauge, exclusive of generating station, cost per mile of double track . . . . . £ 13,400

Darwen, overhead trolley system, 4 ft. gauge, exclusive of power station, total 35,000*l.*, per mile of double track 13,000

Dover, overhead trolley system, 3 ft. 6 in. gauge, exclusive of power station, total 28,000*l.*, per mile of single track 7,000

Manchester (1905), overhead trolley system, current provided by the lighting station, cost per mile of track 12,500
Permanent way, cables, and electrical equipment only, per mile of track . . . 6,575

Portsmouth, overhead trolley system, 4 ft. 7¾ in. 'Scotch' gauge, exclusive of power station, but including taking up old tram lines and concrete foundations and new ditto, cost per mile of double track 21,000
Ditto, including power station and machinery, ditto 23,900

Staffordshire, Bristol, and Coventry, capital expenditure on electric tramways per mile of single track, average 12,000

Wolverhampton, permanent way, electrical equipment, and cables, on the Lorain surface contact system, per mile 8,600

WORKING EXPENSES.	Per car mile. d.
Aberdeen, electric overhead trolley system, including interest on sinking fund	9·00
Birmingham, 1890–1, electric accumulator	9·90
" " cable traction	6·33
" " horse traction	9·79
" " steam traction	10·99
Dover, overhead trolley system, including interest on sinking fund	8·75
London County Council conduit tramways worked on purchased current, in 1905–6	8·02
Staffordshire, Bristol, and Coventry electric trams	6·30
Modern electric trolley lines generating their own current work	5*d.* to 6*d.*
" " " where current is purchased	6*d.* to 7½*d.*

The Peak Cable Tramway, Hong-Kong (1888).—Rises 1,207 ft. in a total length of 4,690 ft. Maximum gradient 1 in 2, and minimum 1 in 25. Three intermediate stations, and top and bottom termini. Single track 5 ft. gauge of two 30-lb. rails, and steel sleepers 24 lbs. per yard. Midway crossing place 130 ft. in the clear, above which the track is formed of three rails. Power-house at summit, with two engines, boilers, etc. Steel haulage cable, 3½ in. circumference, weighing 2 lbs. per ft. run. Rolling stock consists of two cars, each holding 45 passengers, and one ascends while the other descends, 9 minutes per trip. Total cost, 20,000*l.*, or at the rate of 22,516*l.* per mile.

(See p. 689.)

Tube Wells.

Driven tube wells sunk in ordinary ground, including use of tackle, well driver's time, and wrought-iron lap-welded tubes, approximate costs as detailed below; add pumps. The quantity of water obtainable depends on the water-bearing strata, and can be increased by connecting two or more wells together. See also 'Artesian Wells,' p. 2840.

Depth of Tubes, etc.

Estimated Costs, 1930.

		Internal Diameter. 1½ in.	2 in.	3 in.
Not exceeding 15 ft. deep	each	8*l.*	15*l.*	25*l.*
15 ft. to 20 ft. deep	„	10*l.*	17*l.*	28*l.*
20 ft. „ 25 ft. „	„	12*l.*	20*l.*	35*l*
25 ft. „ 30 ft. „	„	15*l.*	24*l.*	43*l.*

35 ft. „ 40 ft. „	„	21*l.*	32*l.*	52*l.*
If beyond this depth, per foot deep		8*s.*	15*s.*	25*s.*
Sand strainers	each	40*s.*	60*s.*	80*s.*
Galvanised perforated driving points in 3 ft. lengths	„	2*l.*	3*l.*	4*l.*
Special point of tough yellow metal for waters impregnated with iron	„	3*l.*	4*l.*	6*l.*
Apparatus for driving tube wells, including sheer legs, ram, pully block, rope, and windlass	per set	20*l.*	25*l.*	30*l.*
Average quantity of water obtained, gallons per hour:		150 to 900;	300 to 1,500;	450 to 3,000.

Description of Pump.

	Size of barrel. 3 in.	3½ in.	4 in.
Standard pump, with valve door, supplied only, each	6*l.*	8*l.*	10*l.*

Tunnels.

Estimated Costs, 1930.

Cost of all tunnelling varies considerably according to locality, nature of excavations, pumping, size and depth of shaft, lining, distance to remove spoil, etc.

Adits.—Headings or tunnels at bottom of shafts, including excavating, removing, and raising material from a depth not exceeding 100 ft., and length of tunnel not exceeding 50 yds. from mouth of shaft, timbering, etc., complete, but exclusive of pumping:—

4 ft. × 6 ft. in clay, gravel, or soft chalk	per ft. run	2*l.* to 3*l.*
do. in hard rock requiring blasting	do.	4*l.* „ 5*l.*

Aqueduct Tunnels.—As constructed in connection with large waterworks:—

Tunnels lined with concrete, 10 ft. diameter	per yard run	70*l.* to 100*l.*

Canal Tunnels.—As for inland navigation by ordinary canal boats, 72 ft. long × 7 ft. wide, average dimensions of tunnels being 16 ft. × 18 ft.:—

Excavation in clay, and lining with brickwork and concrete	per yd. run	50*l.* to 80*l.*
Excavation in rock, and lining with masonry and concrete	do.	80*l.* „ 120*l.*

Irrigation Canal Tunnels.—As constructed in India to convey water from the mountainous districts to the lowlands, the average dimensions being 18 ft. wide by 12 ft. high. The longest is the Swat Canal Tunnel, 11,235 ft., and the next, the Pariyar Tunnel, 5,704 ft.

Irrigation canal tunnels in hard rock	per yd. cube	2*l.* to 3*l.*
„ „ „	per yd. run	40*l.* „ 60*l.*

Railway Tunnels.—Cost depends upon nature of excavations, lining required, etc.:—

For narrow-gauge or metre railways (3 ft. 3⅜ ins.), single track	per yd. run	50*l.* to 100*l.*
For standard-gauge railways (4 ft. 8½ ins.), single track	,,	80*l.* ,, 150*l.*
,, ,, ,, ,, double track	,,	150*l.* ,, 300*l.*

Ordinary Tunnels.—Ordinary tunnelling, cubic rate. It is generally cheaper to tunnel than to make a cutting over 50 ft. deep, but a good deal depends upon whether earth is required for embankments, and upon the kind of ground.

Tunnelling or driving headings, 20–50 ft. sup. sectional area, not exceeding 50 ft. below surface of ground or 50 yds. from shaft or adit, including use and waste of timbering, and drawing spoil to foot of shaft ready for removal :	Per yd. cube. *s.*	*s.*
in ordinary ground, sand, or gravel	9 to	11
in stiff clay or shingle	12 ,,	14
in hard, solid chalk and flints	17 ,,	20
in soft rock not requiring blasting	45 ,,	50
in hard rock requiring blasting	55 ,,	60
Hoisting spoil from foot of shaft to ground surface, for any depth not exceeding 25 ft.	2 ,,	3
Extra only for every additional 25 ft. in height	1 ,,	2
Removing not exceeding ¼ mile, and depositing	4 ,,	5
Filling in, packing, and ramming, including transporting not exceeding 50 yds.	3 ,,	4
Excavating in large tunnels not less than 18 ft. wide × 20 ft. high, including fixing and removing temporary timbering and shoring, and removal of spoil not exceeding 1 mile :		
in ordinary ground, clay, or gravel	20 ,,	30
in soft rock not requiring blasting	30 ,,	40
in hard rock requiring blasting	40 ,,	70

Open Shield Tunnelling.—For subways or tunnels under rivers, with open headings and ordinary atmospheric conditions. Cost includes providing, fixing, and removal of timbering, shield, hydraulic jacks, pumping machinery, electric light, lifting excavated material to surface of ground, etc., but *exclusive* of concrete, masonry, or iron lining to tunnel ; for quantities not less than 3,000 yds. cube.

Open shield tunnelling, 100–200 ft. sup. sectional area, not exceeding 50 ft. below surface of ground nor 300 yds. from mouth of tunnel :	Per yd. cube. *s.*	*s.*
in ordinary ground or sand	50 to	70
in stiff clay or gravel	60 ,,	80
Open shield tunnelling, 200–400 ft. sup. sectional area :		
in ordinary ground or sand	70 ,,	90
in stiff clay or gravel	80 ,,	100
Add for every additional 25 yds. in length	1 ,,	2

Pneumatic (or Closed Shield) Tunnelling.—For excavations in water-logged ground under air pressure, the closed shield having bulk-heads and air-locks, to admit and remove materials, workmen, etc. Cost includes providing, fixing, and removal of timbering, shield, hydraulic jacks, pumping machinery, air-compressing plant, electric light, raising excavated material to surface of ground, etc., but *exclusive* of concrete, masonry, or iron lining to tunnel ; for quantities not less than 3,000 yds. cube.

Pneumatic shield tunnelling, 100–200 ft. sup. sectional area, not exceeding 50 ft. below surface of water or ground nor 300 yds. from mouth of tunnel :	Per yd. cube. *s.*	*s.*
in ordinary ground or sand	100 to	120
in stiff clay or gravel	110 ,,	130
Pneumatic shield tunnelling, 200–400 ft. sup. sectional area :		
in ordinary ground or sand	120 ,,	140
in stiff clay or gravel	130 ,,	150
Add for every additional 25 yds. in length	2 ,,	3

Tunnel Shields.—The cast-iron lining of a shield-driven tunnel is equivalent to about one-third total cost of tunnelling. The shield was first used by Brunel at the Rotherhithe tunnel in 1825, then by Mr. Greathead at the Tower subway in 1869, and the improved 'Greathead' shield in

1884 on the City and South London Railway. It consists of a steel ring with cutting edge, which is pushed forward by hydraulic jacks about 3 ft. apart. Tube railways and subways vary from 11 to 30ft. diameter, with 8–28 jacks per shield, and the tunnelling progresses at the rate of 30–60 ft. per week.

Costs complete with bolts, nuts, hydraulic jacks, etc., but *exclusive* of hydraulic machinery, piping, etc.:

Steel open tunnelling shields complete, 10–20 ft. external diameter, 40*l.*–50*l.* per ton each 1,000*l.* to 4,000*l.*

Steel closed tunnelling shields complete, 12–25 ft. external diameter, 50*l.*–70*l.* per ton each 4,000*l.* to 12,000*l.*

Tunnel Maintenance.—Cost of reinstating 3- to 6-ring double-track railway tunnels, in sand, clay, or chalk, including cutting out the inner ring and replacing by a brindle ring in cement, sometimes an additional ring, or part of the tunnel inverted, toe wall built to the footings, parts of the wall relined, or spaces behind walls and over arches filled with concrete, etc., the work being carried out day and night during traffic by contract or departmentally, a single line run at night, and taking various periods of from three to eight years to complete.

20*l.* to 40*l.* per lineal yard:

Other tunnels requiring more extensive repairs, such as shoring, bad portions cut out, and completely rebuilt, use of cement gun, etc.:

60*l.* to 500*l.* per lineal yard.

TUNNELS (RAILWAY).

TUNNELS. Actual Costs.	Date. Years.	Length. Yds. Run.	Ft. Per Day.	Total in thousands	Per Y.R.
				£	£
Arlberg (6¼ miles), Austria. 2 tracks in single tunnel, 25 ft. 3 ins. wide by 21 ft. high, partly lined with masonry	1880–84	11,210	28	1,204	107

Mont Cenis (7⅞ miles), France to Italy. 2 tracks in single tunnel, 26 ft. 3 ins. wide by 24 ft. 7 ins. high. Through solid granite, brick and stone lined .	1857–71	13,712	9	2,880	210
Severn (4⅓ miles). 2 tracks in single tunnel, 26 ft. wide by 24½ ft. high, lined with 3 ft. brickwork. Water-logged ground and expensive pumping. Ventilated by fan 40 ft. diam. Hawkshaw, Hayter, and Richardson, engineers	1879–86	7,674	6	2,250	293
Simplon (12½ miles), Switzerland to Italy. 2 single-track tunnels, each 16 ft. 5 ins. wide by 19 ft. 6 ins. high, 56 ft. apart axis to axis. Enlarged in 1911, at 1,600,000*l.* A. Brandt, engineer .	1898–1906	21,578	28	3,120	145
St. Gothard (9⅛ miles), Switzerland to Italy. 2 tracks in single tunnel, 26 ft. 3 ins. wide by 24 ft. 7 ins. high, in granite and lined with masonry. Louis Favre, engineer	1872–82	16,426	18	2,300	140

WATERSHEDS.

Afforestation at Torquay (1923–28).—Watersheds at South Teign and Tottiford, near Torquay, for the intake of the waterworks conduit. 720 acres, 40 acres being planted per annum, and 278 acres previously since 1899. The cheapest and best way of obtaining trees was to buy two-year-old seedlings, ranging from 7*s.* to 15*s.* per 1,000, which were placed in the corporation nurseries for eighteen months at a net cost of 4*s.* per 1,000. The trees were then planted out into permanent positions in the watersheds at a cost (in 1928) of 10*l.* to 12*l.* per acre, towards

which the Forestry Commission made a grant of 2*l.* per acre. 120,000 seedlings were purchased each year, and the varieties were :—Japanese larch, Douglas fir, Sitka spruce, Norway spruce, Austrian pine, Scotch fir, silver fir, ash, beech, and sycamore. The soil of the watersheds was of a light loamy nature, and fairly sheltered by hills. The whole cost of afforestation was paid out of revenue, and the work done by the corporation's regular staff under a forester, the areas being protected by wire-netting because of rabbits, which added to cost. When the trees make progress a considerable revenue is made of the poles from the thinning out of the plantations each year, as there is a good demand for this class of timber from nurserymen for general rustic work.

Water Towers.

Water towers, brick, exclusive of tanks and pipes, 1*s.* to 1*s.* 4*d.* per ft. cub., 2*s.* to 5*s.* per gal.
Water supply inside a building, including service pipes, taps, etc. 2*l.* 10*s.* to 3*l.* per tap.

Beverley Water Tower, Yorkshire (1915).—Built of reinforced concrete on the Hennebique system. Two circular tanks, one within the other, the inner one holding 4,000 gals. and the other 7,200 gals., or a total of 11,200 gals. Extreme diameter 34 ft., and 10 ft. internal depth, with three 6-in. cast-iron outlets, 4-in. sides, 2-in. curved dome top, 4-in. bottom, with beams under, supported on three 12-in. × 12-in. columns or legs, 30 ft. high, with 12-in. × 8-in. braces to latter and half-way up. Total height from ground level to top of tank, 42 ft. 6 ins. Concrete foundations, 2 ft. deep. Cost, including materials and erection, 312*l.*, or 27*l.* 17*s.* per 1,000 gals.

Bramham Moor Water Tower, near Tadcaster, Yorkshire (1916).—Designed by the Trussed Concrete Steel Co. Two united rectangular tanks, 4,000 gals. and 6,000 gals., or a total of 10,000 gals.; two iron ladders inside the tanks for cleaning purposes, and 3-in. cast-iron outlets; 5-in. sides, 3½-in. flat top, 6-in. bottom, with 24-in. × 10-inch beams under, supported on four 10-in. × 10-in. columns or legs, 20 ft. high, with 10-in. × 6-in. braces to latter and half-way up. Foundations 2 ft. 6 ins. deep in addition. Cost, including materials and erection, 298*l.*, or 29*l.* 16*s.* per 1,000 gals.

Curragh Water Tower (1900).—Heavily built, 34 ft. square externally and 94 ft. high above ground. 6 stories. Concrete foundations 6 ft. thick, brick walls in cement 45 ins. thick below to 22 ins. at top. Flat concrete roof, asphalted. Contains two cast-iron tanks, 20,000 gals. each, or 40,000 gals. total. Lower floors used as a fire engine station. Building only, 9,300*l.*; cast-iron tanks and pipes ,1,630*l.*; special fittings, 70*l.* Total, 11,000*l.*
1*s.* 4*d.* per ft. cube. 275*l.* per 1,000 gals.

Waterworks.

Waterworks, comprising reservoirs, filter beds, mains, valves, hydrants, etc., complete:

	£	
Birmingham	3	per head of population.
Dublin	2	" "
Edinburgh	3½	" "
Glasgow	3	" "
Liverpool	4	" "
Manchester	3	" "
Generally speaking	2*l.* to 4	" "
Small waterworks in Ireland (20 to 25 gals. per head.)	2*l.* to 2½	" "

Batticaloa Water Supply, Eastern Province, Ceylon (1915–16).—Supplies a population of 6,000 with about 20 gals. per head per day. One central well 10 ft. diameter, and two auxiliary wells same diameter, connected by adits 500 ft. long, yielding 180,000 gals. per day. From the central well the water is pumped through a 7-in. steel delivery main to the reservoir, 4 miles distant, from which the town is supplied by gravitation by 2-in. and 1½-in. distributing mains to 75 standpipes. 11¼ miles of pumping and service mains altogether. Pumping machinery in duplicate, 3-in. centrifugal pumps, belt-driven by 18 B.H.P. oil engines, each pump capable of delivering 10,000 gals. per hour against a total head of 60 ft., or a total pumping capacity of 100,000 gals. per diem working 10 hours. Wells lined with 12-in. concrete, roofed with concrete slabs. Storage reservoir of 100,000 gals., with concrete walls faced in brick cement rendered and roofed with corrugated iron on steel trusses. Cost, 9,533*l.*, or 95*l.* per 1,000 gals., or 1*l.* 12*s.* per head of population supplied.

New Magdalen Barracks Water Supply, Oxford (1896).—Supply from City of Oxford Water Company's mains, constant service, Siemens' meter supplied by Company. Davey's lift and force pump worked by steam power, and 6 in. cast-iron mains, 3 in. cast-iron domestic supply mains, and 1½ in., 1 in., ¾ in., and ½ in. galvanised wrought-iron service pipes, 3 to 4½ ft. deep. Reserve tank of 13,000 gals. for fire purposes, 60 ft. high on Armoury roof, 18 fire hydrants, 20 sluice valves, 40 stop valves, 280 bib valves, 50 3-gal. flushing cisterns to w.c.'s, and 6 200-gal. cisterns to latrines. Occupation of barracks, 500 adults, 100 children, and 5 horses. Total cost, including 800*l.* for machinery and erection, 3,500*l.*, or 5*l.* 16*s.* 8*d.* per head of occupation, exclusive of horses. 6*s.* 6*d.* per yd. run of excavation, exclusive of machinery, but inclusive of all fitments.

(See also p. 1418.)

IMPOUNDING RESERVOIRS.

Impounding reservoirs for gravitation waterworks to large towns, including excavations, embankments, etc.

200*l.* to 700*l.* per million gallons storage.

	£	
Arnfield, for Manchester waterworks	432	per million gals. storage.
Crowden " "	561	" "
Hollingworth " "	458	" "
Tellowfold " "	722	" "
Monmouth	912	" "
Rooden, for Oldham	491	" "
Sheffield waterworks, structure only	210	" "
Ditto, including Parliamentary expenses, payments for compensation, etc.	485	" "
Swansea	550	" "
Swinshaw, for Ashton-under-Lyne and Stalybridge	405	" "
Walshaw Dean, for Halifax	469	" "

Curragh Old Waterworks Pumping Station.—Different dates, 1859, 1907, 1915, and 1921. Includes concrete reservoir, corrugated iron fence, brick engine house, boiler house, chimney shaft, workshop, coal yard, engineer's cottage, and new corrugated iron engine shed, engineer's hut, concrete tanks, old and new wells with bored Artesian tubes, 112 ft. and 276 ft. total depths respectively, barbed wire fencing, water-main connections, and 1,550*l.* worth of machinery, complete . . . . . 9,550*l.* total cost.

13½-in. Artesian bored tube well (1907), including boring 52 ft. deep sunk in sand and gravel from the bottom of existing dug well which is 8½ ft. diameter and 59 ft. deep . . . . . 3*l.* 5*s.* per ft. in depth.

Ditto including men's time, fixing plant, testing, and carriage, and hire of compressor . . . . . 7*l.* 10*s.* ditto.

(The cost of this Artesian well is included in the 9,550*l.* total.)

Curragh Old Waterworks Reservoir (1887–93). In connection with pumping station. Uncovered, with puddle clay embankments, stone-lined. Steel fence all round. Size, 320 ft. × 260 ft. × 6 ft. deep, and holds 3,100,000 gals. Total, 2,760*l.* 1½*d.* per foot cube.

Reservoir now disused . . . . . 18*s.* per 1,000 gals.

Selby Waterworks Reservoir (1908). 800,000 gals. 12-in. concrete floor, brick walls, 50½ ins. thick at base and 22½ ins. at top, 6-in. concrete roof in arches of 7 ft. span. Total, 4,800*l.* . . . . . 6*l.* per 1,000 gals.

In the London Metropolitan area—

Cost of pumping averages 43 per cent. of the entire maintenance expenditure.
Cost of pumping alone averages 50*s.* per million gallons.
Repairs and renewals of water-mains and pipes, 34*s.* per million gallons.
Maintenance of water-mains or pipe-way, 24*l.* per mile.
Cost of filtration, 7*s.* 5*d.* per million gallons.

Assuan Dam (1898–1902 and 1907–12).—The Assuan or Aswan Dam was built for irrigation purposes at the head of the first cataract of the Nile, about 600 miles from Cairo and 350 miles above the Assiout barrage. It was formed across 5 channels of the river, which flowed at the rate of 16 miles an hour, and constructed of local granite masonry in Portland cement, on a similar rock foundation which had dykes of softer igneous material. The original dam was 1½ miles or 6,600 ft. long, 100 ft. thick at bottom, tapering to 24 ft. at top, with a maximum height of 130 ft. from base. Total weight of stonework over a million tons; 180 sluice openings, closed by steel gates; 1,000 Europeans and 20,000 natives were employed. The barrier affected the Nile for 140 miles higher up, and turned it into a regular lake. The greatest difference of level of water above and below the wall was 67 ft., and navigation was provided by a ladder of five locks, each 260 ft. long and 32 ft. wide. This first dam was completed in 1902, and held about 250,000 million gallons, which brought over a million acres of desert under cultivation. Engineer, Sir Wm. Willcocks, and contractors, Sir John Aird & Co. Cost was 2,500,000*l.* constructional work and 2,000,000*l.* for land and compensation charges, or 4,500,000*l.* altogether. This latter is equivalent to 18*l.* per million gallons of storage capacity, or 4*l.* 10*s.* per acre of irrigation area.

Between 1907 and 1912 the foregoing original dam was raised an additional 23 ft., thickened by 16 ft. on the downstream side, lock walls widened, and new dock gates provided, so that the impounding reservoir or lake was now 240 miles long, and the storage capacity increased by an extra 310,000 million gallons. Another million acres were also brought under cultivation. The greater depth submerged the Philae temples well up the river. Sir Benjamin Baker was consulting engineer. Cost of extension, including land and compensation charges, was 1,500,000*l.*, equivalent to 4*l.* 17*s.* per additional million gallons, or 1*l.* 10*s.* per additional acre.

Total present capacity as enlarged, 560,000 million gallons, bringing two million acres under total irrigation, at a total cost of 6,000,000*l.* This is equivalent to an average of 10*l.* 14*s.* per million gallons, or 3*l.* per acre of irrigation, as finally completed.

Burrinjuck Dam (1909-20).—Or Barren Jack. The highest dam in the Empire and in the Blue Mountains of New South Wales, at the confluence of three rivers—the Murrumbidgee, the Goodradigbee, and the Yass, which the dam ponds up 40 miles, 13 miles, and 19 miles respectively. The artificial lake so created has a surface area of 20 square miles, or 12,800 acres, and is 220 ft. greatest depth, giving a capacity of over 33,000,000,000 cubic ft., or about 206,250,000,000 gallons. The dam is a massive wall in a deep gorge with cliffs 1,000 ft. high and only 300 yds. apart, the sides being so steep that it was impossible to establish workshops upon them, and it was also across the bed of a river subject to floods. The granite masonry is 236 ft. high from rock to crest, set in cement, and 186 ft. thick at base, tapering to 18 ft. at top. The dam is of the arch type with convex side turned up stream; radius of curve 940 ft. and length of arc 900 ft. Flood-water tunnel 14 ft. × 13 ft., and two culverts cut through the cliffs at the ends of the dam itself. The water had to be conveyed 260 miles, and then distributed by miles of canals over 1½ million acres of parched land, allowing the conservation of water for some 2,000 farms. Total cost about 3,000,000*l.*, or 14*l.* 11*s.* per million gallons of storage capacity, or 2*l.* per acre of irrigation area.

Croton Dam (1896–1911).—Or the Cornell Dam, which holds up the waters of the Croton River to form the great Croton lake reservoir which supplies New York with water, 33 miles away. A diversion canal, 1,000 ft. long and 2,000 ft. broad, was first excavated to divert the river before the dam itself could be commenced. The latter is about 1,200 ft. long, a maximum width of 216 ft., and greatest height 300 ft. from rock to crest, making it the highest in the world. It contains 833,000 cubic yards of masonry, and required 1,500,000 cubic yards of excavation. Owing to the rock being rotten, the foundations were carried in places 130 ft. below river-bed. Spillway built of granite blocks, some weighing 10 tons each. The lake behind the dam is 20 miles long, and contains 32,000,000,000 gallons of water. Three villages and numerous isolated buildings and farms were cleared away, and 75 miles of stone wall built round the reservoir. The outlay was excessive, as a large part was due to alterations and work which had to be afterwards undone, including the removal of the first core wall and taking up the earth on either side of it. Total cost about 1,600,000*l.*, or 50*l.* per million gallons of storage capacity.

Wentwood Reservoir, Newport (1894–1904).—Situated at Llanvaches, some ten miles from Newport, Monmouthshire. It has a water area of 41 acres, a depth of 86 ft., and a capacity of 410,000,000 gallons. The great dam, which is 456 ft. above sea level, is 97 ft. high, 800 ft. long, and 700 ft. wide at base, gradually tapering to 30 ft. wide at top. The inside slope is pitched from top to bottom. The valve tower and outlet are placed quite independently of the dam at the eastern end, and the culvert, which runs for a length of 900 ft. through the dam, is 6 ft. diameter and carries two water mains. Water is drawn into the reservoir from two streams in the Newchurch valley by means of a tunnel, which ranges from 3 ft. diameter at the Newchurch end to 6 ft. at the reservoir end; length of tunnel, 3,683 yds. Total cost, about 390,000*l.*, or 951*l.* 4*s.* per million gallons of storage capacity.

Scraping Water Mains.

Ayr.—Scraping 14-in. and 16-in. cast-iron water mains, 14½ miles long, at Ayr, between Loch Findas and the service reservoir at Dalrymple, in 1915. Pipes laid 28 years before, but incrustation reduced capacity by 30 per cent. Scraper weighed 3 cwts., and was driven by a pressure of 15 ft. head of water. When this pressure was unobtainable the instrument was pulled through by a chain. Pipes were divided into sections with inspection boxes, and each section was done twice, the scraper travelling at the rate of 2 miles an hour. Capacity of mains was at once increased by 37 per cent.

For 14-in. pipes the scraping alone cost 13*l.* 8*s.* per mile, or 2*d.* per yd. run.
„ 16-in. „ „ „ 12*l.* „ „ 1⅜*d.* „
„ 14-in. pipes the total cost was 34*l.* 5*s.* „ „ 4⅜*d.* „
„ 16-in. „ „ „ 46*l.* 10*s.* „ „ 6½*d.* „

Scraping is necessary every 3 years, owing to rapid reincrustation.

Prestwick.—Scraping 6 in., 8 in., and 10 in. water mains leading from the filters to the town, in 1923. In all 7,100 lin. yds. of pipes were scraped, and over 8 tons of corrosion removed. The pressure heads after scraping, as taken at air valves along the mains, showed an increase overall of 20 ft. The cost worked out at 1*s.* 5*d.* per yd. run.

Cleaning.—Cleaning 4 in. water main by the patent Powrcleer apparatus, supplied by the British Pipe Cleaning Co., W. & J. Glossop, Hipperholme, Halifax, for a minimum quantity of 1 000 yds., 1*s.* 4*d.* per yd. run (August 1922).

Torquay (1927).—Old water mains, cast-iron spigot and socket pipes, varying from 3 in. to 12 in. diameter, and total length 200 miles. Scraping cost 15*s.* per mile, at a usual rate of 3 miles per hour.

Various Towns.—Actual cost by pipe scraper driven by water pressure and supplied by Glenfield & Kennedy, Ltd., Kilmarnock:—

Year.	Place.	Diam. of Main.	Length of Main.	Total Cost.	Cost per Mile.	Cost per Yd. Run.	Obstructions removed, other than corrosion.	Gain in Delivery after Scraping.

SECTION XLVI

DEPRECIATION OF PLANT AND MACHINERY—INCOME-TAX ALLOWANCES

(Contributed by Alfred B. Searle, Vice-Pres. Valuers' Inst., Licensed Appraiser and Valuer.)

SECTION XLVI

DEPRECIATION OF PLANT AND MACHINERY—INCOME-TAX ALLOWANCES.

(Contributed by Alfred B. Searle, Vice-Pres. Valuers' Inst., Licensed Appraiser and Valuer.)

Depreciation is a term applied to the reduction in value which occurs in plant or machinery, no matter whether they are in use or stored. The amount of depreciation is affected by the condition in which they are kept and by the availability or otherwise of more suitable appliances.

The loss in value is most properly met by an annual charge (to which the term 'depreciation' is commonly applied); the total of such charges should, when the appliance is worn out, discarded, or replaced by another, be equal to the difference between the original cost and the sum obtained (if any) by the sale of the worn-out or discarded appliance. Thus if a machine costing 1,000*l.* is discarded as useless after ten years and then is sold for only 10*l.* the total depreciation is 990*l.*, the annual depreciation is 99*l.*, and the residual value is 10*l.* The depreciation may be affected by any sums spent on renewing parts of a machine or plant, though these are usually charged separately in the accounts, as *renewals*.

Deterioration is the loss in value due to the lapse of time and to the use of the appliance. It occurs more rapidly when a machine is used than when it is stored under good conditions, but may be just as serious if a machine is stored under unsuitable conditions. In deterioration is also included the loss in value which occurs directly the ownership of anything has been transferred from the seller to the buyer, the 'second-hand value' being always less than the market price when new; the difference forms part of the loss by deterioration.

Obsolescence is the loss in value which occurs when a more suitable appliance can be used for the same purpose. It occurs when a machine is discarded, long before it is worn out, because another machine is more profitable to use.

Renewals are the cost of replacing worn-out or damaged portions of machinery or plant. To some extent they reduce the depreciation, but for convenience are usually treated quite separately. The Inland Revenue officials, for some purposes, take renewals instead of depreciation when calculating allowances for income-tax assessments. Thus, instead of allowing 3*l.* per annum as the depreciation on a typewriter, they allow nothing until the typewriter is replaced by another one; then they allow the cost of the new machine less the sum obtained by the sale of the old one, or a sum estimated to be obtainable for it.

Residual Value is the value of a machine or plant at the end of a given period—usually, but not necessarily, when it is worn out or discarded. In dealing with the estimated life of plant or machinery, the residual value of such plant or machinery when its period of usefulness has expired must be taken into account, and with plant of special nature it may generally be assumed that in proportion to its special character its residual value will be low. Plant of general character, engines, boilers, shaftings, pulleys, etc., carries a high residual value in the event of displacement.

Diminishing Value is the reduction in the value of plant or machinery as the result of depreciation or obsolescence, or both. The term is also used to indicate the value obtained by deducting depreciation for one year at a given rate, and then applying the same rate to the reduced value so obtained. Thus, if a machine costing 1,000*l.* is depreciated at 10 per cent. per annum on the diminishing value it will be worth 900*l.* at the end of the first year, 900*l.* — 90*l.* or 810*l.* at the end of the second year, 810*l.* — 81*l.* or 729*l.* at the end of the third year, and so on. This method is largely used because of its convenience, but it requires a larger rate of depreciation than when the rate is calculated throughout on the original value. In recent years there has been a tendency to revert to the basis of original cost. For instance, a rate of 10 per cent. on the original cost will

exhaust the value in ten annual instalments; but a rate of about 16⅔ per cent. would be required to exhaust the value in the ten years if calculated on the diminishing value remaining after the deduction of depreciation in each year.

The argument in favour of basing the calculation on the diminishing value is that the sums written off in the earlier years were greater when the repairs were small, and this tended to equalise matters. Too often, however, the two factors of rate and basis have not been settled together, and consequently the basis of diminishing value has had the effect of leaving a considerable value in the books when the plant has disappeared. For instance, a 5 per cent. rate generally carries the impression of a twenty years' life, yet taking 100*l.* as the cost, and writing off on the diminishing value, the balance left at the end of the twentieth year is 37*l.* 14*s.* After twenty-one years' service the residual value of the plant would be, roughly, one-third of the first cost, a figure far too high in most cases. Besides, by adopting the basis of original cost, the position is much clearer for any revision of the rate at any subsequent period.

Rate of Depreciation.—This is usually expressed as a percentage of the original value of the plant or machinery, or on what is known as the diminishing value. The rate of depreciation is based on the assumed durability of the appliance, on its residual value, and on whatever allowance should be made for its becoming obsolescent before it is worn out. The determination of the rate of depreciation of various kinds of machines, etc., requires special skill and experience, and has given rise to specially trained appraisers or valuers, each of whom has expert knowledge of certain classes of plant or machinery; a valuer who is an expert on brewing appliances would probably know little of cotton-spinning, bricks, or presses, and *vice versâ*. It is, therefore, important that valuations should be made by men of *special* knowledge and not (as is usually the case in valuations for rating assessments and some other purposes) by men with only a general knowledge.

As different parts of a plant and different machines wear out or become obsolescent at different speeds, it is desirable to decide on a rate for each separate machine or appliance, though some grouping is desirable.

There is much difference of opinion as to what are suitable rates of depreciation, especially when accurate data on which to base them are not available. The following figures are only approximate, but they give a useful *general* idea, which may be greatly modified in particular cases.

Motive Power, Boilers, Engines, etc.—Some authorities place the depreciation on engines as high as 12½ per cent., and boilers at 10 to 15 per cent. Much depends on stress of working and the water. Mathieson places the life of a boiler at fifteen years, with renewal of the furnace at the end of ten years, and recommends a rate of 7½ per cent. per annum on the diminishing value on this class, no provision being made for obsolescence. This is, however, an extreme view.

Power Transmitters.—Shafting, pulleys, and plant under this head have, as a rule, a high residual value, even if displaced, and a rate of 5 per cent. will usually be found sufficient. Belting should be classified as loose tools. In this class a rate of 10 per cent. would be desirable. No provision is made for obsolescence.

Process Plant, Fixed.—Under this head would be placed all heavy process plant, the renewal portions of which are classified under their separate heading. The deterioration would then be met by a rate of 2½ per cent., the renewal rate at 2½ per cent. An obsolescence rate depending on the nature of the processes will also be needed; it may be 6 per cent.

Process Plant (Wearable).—For this it is necessary to provide a heavy renewal rate. By the dissection of this plant the separation of the different details can be secured, and it is easy to apply to each a distinctive rate for renewals applicable to its character and requirements, based on experience. It will usually be at least 10 per cent.

Process Plant (Loose).—In the case of loose tools, the yearly valuation gives the most reliable results. In some cases there is an annual increase in this class, but this should verify itself. It is to be remembered that at a going-concern valuation this cannot, in the nature of the plant, work out at more than half the original cost value.

Accessory Plant.—Usually has a high residual value due to general utility, and consequently a rate for deterioration of 2½ per cent. and a renewal rate of 5 per cent. should suffice.

Horses, Carts, Harness, etc.—The risks and depreciation on this class are too great to include in any average rate. A revaluation annually gives probably the best results.

The following rates of depreciation have been authorised by the Government of Australia in connection with the Federal income-tax on industrial establishments:—Boilers, 5 per cent.; boring machinery, 10 per cent.; cables, aerial, 7·5 per cent.; cables, underground, 2·5 per cent.; condensers, 5 per cent.; cranes, 5 per cent.; elevators, electric, 7·5 per cent.; elevators, hydraulic, 10 per cent.; engines, steam, 5 per cent.; foundry cupolas, 15 per cent.; furniture, 5 per cent.;

generators, 5 per cent.; machine tools, 5 per cent.; machinery used in ordinary manufacturing, 5 per cent.; meters, switchboard, 7·5 per cent.; motor trucks, 10 per cent.; patterns, 15 per cent.; pumps, 5 per cent.; galvanised iron tanks for rain water, 5 per cent.; galvanised iron tanks for other water, 10 per cent. The figures are based on the *diminishing value* of the assets and not on their original cost.

The following table, by Preece, gives (A) the approximate life in years of the various classes of machinery, etc., in an electrical undertaking if properly maintained, and (B) the probable residual value at the end of that term in per cent. of original cost. It affords a useful means of checking any suggested rate of depreciation on the appliances, etc., mentioned, but is very incomplete and tends to include figures in column A which are too large for present-day conditions.

	A.	B.		A.	B.
Foundations	100	nil	Cables (solid in wood trough)	40	12
Buildings	80	nil	Buildings (sub-station)	50	nil
Boilers (water tube)	25	5	Sub-station equipment	25	12
Boilers (Lancashire)	22	3	Accumulators	15	10
Dynamos and alternators	30	8	Arc lamp-posts	40	5
Engines and other machinery	25	6	Arc lamps	12	5
Cables (armoured)	35	15	Electric motors	25	9

Methods of Estimating Depreciation.

Appraisers and valuers have various methods of estimating the depreciation of plant and machinery, and two men of equal skill may not agree in their estimate because they use a different method, or because they have different ideas as to the durability of a particular appliance; the latter affects the rate of depreciation. The two methods generally adopted are: (1) To assume a definite rate of depreciation on either the plant and machinery as a whole or definite rates for each part thereof, and to deduct this from either the original cost or the book value. (2) To value each individual part of the plant and machinery each year and write off the difference in value from that of the previous valuation. The Inland Revenue officers usually employ a third method, based on renewals.

All these methods are faulty. In the first the result is hazardous, especially if based on a single rate of depreciation on the whole plant and machinery, because different parts depreciate at different rates, and no single figure or 'average' can be accurate. Even if the plant and machinery are divided into groups or each individual item is taken separately errors may still occur, as it is by no means easy to find an accurate rate of depreciation for some appliances. In the second method an independent valuer is essential, and the method is therefore costly. A common device is to use the first method, applied to the plant and machinery after dividing it into five or six groups, and to adjust this by a revaluation by an expert every five years. This is probably the best compromise between accuracy and cheapness.

When the first method alone is used, a distinction must be made in the rate of depreciation, according as this is deducted from the original cost of the appliance or from its diminished value (see *ante*).

Fire Insurance and Depreciation.—Whilst it is a sound, general policy to write as much off for depreciation as possible, such a course has an adverse effect on insurance against fire, as the value in the case of a fire would be affected in the claim for replacement. It is usual in some offices to append a declaration on the face of the policy that the depreciation written off in the books shall not be taken for the purpose of assessing a fire loss. Usually the assured is covered for the value of the plant at the time of the fire, and that the original cost of the plant, less depreciation, is not necessarily the basis of the claim. There appears to be no scale of depreciation in force for different kinds of plant recognised by the insurance companies, but these losses are generally settled as between the assessors and surveyors acting for both parties, or, failing their agreement, by arbitration: no special rates are applicable, but each case is settled on its merits. The principal factor appears to be the possession of definite and specific information on the value and cost of the plant, and the rate of depreciation should not in any way govern the claim in case of fire.

It is a general provision in fire insurances and policies that the company may elect to replace the plant; instances of this have rarely occurred, if ever, and probably the replacement clause was never intended as other than a protection to the insurance company.

Depreciation and Income-Tax.—The rate of depreciation allowed by the inspectors appointed under the Income-tax Acts differs considerably in different localities. For instance, the rate of depreciation allowed to engineers in Leicester is 7½ per cent. on the full value, while in Cardiff the rate is only 5 per cent. on the diminished value. Hosiery machinery in Leicester obtains 7½ per cent. as against 5 per cent. on lace machinery in Nottingham. Dyers' machinery in Leicester can get 10½ per cent., if justified on inquiry. Generally speaking, a distinction is made between motive

power and process plant, and the general practice assumes 5 per cent. on motive power and 7½ per cent. to 10 per cent. on process plant; these allowances are in respect of both deterioration and renewals.

The Inland Revenue authorities have now reverted, in a number of cases, to the basis of original cost, and where, say, 5 per cent. is allowed on original cost, there is an alternative rate of 7½ per cent. allowed on diminishing value.

On *Fixtures* no allowance for depreciation is made, unless they are included under the head of plant. Any replacements are allowed in full against the year's working.

Renewals.—The practice adopted by the income-tax authorities provides for the charging up of renewals to capital account where depreciation is allowed, and they usually decline to allow both renewals and depreciation out of the year's profits. They will, however, permit, as an alternative to the allowance for wear and tear and obsolescence of plant and machinery, the cost of renewing plant and machinery, under Schedule D. When this course is adopted, the amount to be allowed is the actual cost of the new plant and machinery (excluding any part of such cost which is attributable to additions or improvements, *i.e.* to an increase in capital) after deducting the scrap value or realised price of the plant and machinery replaced.

Example (*a*).—A machine which originally cost 1,000*l.* is worn out and replaced by a machine of similar power or size or capacity which now costs 1,500*l.* The whole of this expense of 1,500*l.* less, say, 100*l.*, the scrap value of the old machine (making a net amount of 1,400*l.*), is allowable from the profits of the year in which it is incurred.

Example (*b*).—A machine which originally cost 1,000*l.* is worn out and replaced by one of greater power or size or capacity costing 2,500*l.* The amount to be allowed as an expense is in this case not the full 2,500*l.*, but only the cost of replacing the old machine by one of similar power of capacity, say, 1,500*l.*, less the scrap value of the old machine.

Although this method of allowance is alternative to the wear and tear allowance for the same class of plant, the two principles may run concurrently for different classes of assets in the same business. For example, the wear and tear allowance may be applied to fixed machinery, and the renewal method used for loose plant.

Example (*c*).—Assuming the total written down value of the trader's plant and machinery before the sale of the obsolete machine to be 10,000*l.*, the new machine to cost 1,400*l.* and the old one to be sold or 400*l.*, future wear and tear allowances will be made upon a value of 11,000*l.*, thus :—

	£
Written down value of total plant, etc.	10,000
Deduct written down value of the obsolete machine . .	400
	£9,600
Add cost of new machine	1,400
	£11,000

The *Wear and Tear Allowance* was formerly based on the average of the preceding three years' trading, but in 1927 this was stopped and since then only the preceding year is taken into account.

If the allowance for wear and tear exceeds the assessable profits, the excess may be carried to the following year's assessment. Thus :—

	£
Gross assessment, 1927–8	6,000
Wear and tear allowance, 6,500*l.*, of which 6,000*l.* is allowed for 1927–8 and 500*l.* is carried forward . . .	6,000
Net amount on which tax is payable for 1927–8 . .	nil
Gross assessment, 1928–9	7,600
Wear and tear allowance, 6,800*l.* for 1928–9 plus the unexhausted balance carried forward for 1927–8, 500*l.* .	7,300
Net amount on which tax is payable for 1928–9 . .	£300

The 'renewal allowance' has been made statutory by each Finance Act since 1918.

ADDENDUM.

LEGAL NOTES FOR ENGINEERS

Contributed by W. Valentine Ball, O.B.E., M.A., Barrister-at-Law, A Master of the Supreme Court.

Author of 'The Law Affecting Engineers' (Constable & Co.); 'The National Form of Building Contract' (published by The Local Government Journal), and Joint Editor of 'Emden's Building Contracts,' 4th Edition (Butterworth & Co.).

SECTION XLVII

LEGAL NOTES FOR ENGINEERS.*

(Contributed by W. Valentine Ball, O.B.E., M.A., Barrister-at-Law, A Master of the Supreme Court.)

(1) Legal Status of an Engineer. (2) Fees. (3) Employment of an Engineer. (i.) *Generally*; (ii.) *Employment Abroad*; (iii.) *Wrongful Dismissal*; (iv.) *The Restrictive Covenant*, (v.) *Engineers and Compensation for Accidents*; (vi.) *Engineers and the National Insurance Act*; (4) Secret Commissions. (5) Disclosure of Secrets. (6) Rights of an Engineer to the Inventions of a Servant. (7) The Engineer as Witness. (i.) *Generally*; (ii.) *Arrangements as to Fees*; (iii.) *Evidence before Parliamentary Committees.* (8) Liability for Negligence. (9) Rights, Powers, and Duties of an Engineer under a Contract for Works. (i.) *Generally*; (ii.) *Specifications*; (iii.) *Plans and Drawings*; (iv.) *Extras*; (v.) *Certificates*; (vi.) *Penalties and Bonuses*; (vii.) *Defects, Repairs, and Maintenance*; (viii.) *Subcontractors and Specialists*; (ix.) *Whether the Employer's Engineer can act as Arbitrator in Relation to Disputes Arising under a Contract.* (10) The Engineer as Arbitrator. (i.) *Generally*; (ii). *Who may be Arbitrator*; (iii.) *Proceedings before the Arbitrator*; (iv.) *The Award*; (v.) *Time for Making the Award*; (vi.) *The Fees of an Arbitrator*; (vii.) *Stating a Case for the Opinion of the Court*: (viii.) *Costs of a Reference.* (11) Notes on Sale and Purchase of Machinery.

(1) LEGAL STATUS OF AN ENGINEER.

Any person may describe himself or practise as an engineer, as the word engineer is not a term of art in the legal sense. Although the Institution of Civil Engineers may make rules of professional etiquette to be observed by its members, compliance with such rules will not be enforced in a court of law, save in so far as they involve a restatement of the ordinary law. For instance a rule which states that no consulting engineer shall advertise could not be enforced, whereas infringement of a rule that 'he shall not pay by commission or otherwise anyone who introduces clients' might offend against the common law (*Panama Telegraph Co.* v. *India Rubber Co.* (1875) L. R. 10 Ch. 515) or against the Secret Commissions Act.

(2) FEES.

If an engineer is consulted, there is an implied contract to pay him reasonable remuneration (*Manson* v. *Baillie* (1855) 2 Mac. H. L. Cas. 80). It is more satisfactory, however, to provide for payment of fees beforehand. In the case of a contract to design and supervise erection of works it is well to provide for payment of ⅓ on signing the contract, ⅓ when half the contract price has been paid to the contractor, and ⅓ when the contractor has been fully paid. Provision should also be made for (1) payment for plans and drawings in case the works are abandoned; (2) travelling and hotel expenses. There is, of course, no fixed scale of remuneration for the engineer, but in deciding what is a reasonable charge, the Court would have regard to (i.) the standing of the engineer; (ii.) the nature and extent of the work undertaken and carried out. It is no answer to a claim for fees (*a*) that a particular undertaking has proved to be a failure if the failure was not due to any fault of the engineer—as where, for instance, an engineer is employed merely to *supervise* the erection of a dam which bursts on completion; or where an engineer is employed to draw plans for a newly invented machine which fails to work (*aliter* if the employer was relying on the engineer's skill and judgment: *Duncan* v. *Blundell* (1820) 3 Stark. N.P. 6); (*b*) that the work in question is not completed, if the failure to complete is not due to the engineer. Where an engineer is to be paid on completion and the work is abandoned before the time, the engineer is entitled to what is due for services rendered, and to what he has lost by not being allowed to complete the contract (*Horton* v. *Hemsley* (1908) *Times*, February 19).

* See also 'Legal Points for Road Engineers,' p. 827.

(3) EMPLOYMENT OF AN ENGINEER.

(i.) **Generally.**—Where an engineer is to be employed for more than a year certain, the agreement must be in writing; and this is so, even if the employment is terminable at any time by six months' notice on either side (*Hanau* v. *Ehrlich* (1912), A.C. 39). The document must set forth all the terms. It is safer, however, to have the terms of an agreement always put into writing. Special care should be taken to (*a*) specify the times when the salary is to be paid; (*b*) provide for the contingency of illness, as illness does not necessarily determine the contract, nor will it justify dismissal without regular notice, unless the employee is so smitten with disease that he can never be expected to work again (*Cuckson* v. *Stones* (1858) 1 E. & E. 248); (*c*) provide for the notice which may be given on either side to determine the contract. If nothing is specified in the agreement, an engineer employed at a yearly salary is entitled to a year's notice (*Buckingham* v. *Surrey and Hants Canal Co.* (1882) 46 L. T. 885). An engineer wrongfully quitting his employment without notice forfeits the salary due for the part of the current year which he has served. The fact that a contract of employment for an indefinite period contains no express term as to notice to be given for its determination does not exclude the implication that such a notice is required (*Payzu* v. *Hannaford* 34 T. L. R. 442). The suspension of servant from his duties which prevents his earning his commission may amount to a wrongful dismissal (*Rubel* v. *Vos*, 34 T. L. R. 171). Dismissal without notice is only justifiable in a case of gross misconduct. If the 'employer' is a company or a municipal corporation or other local authority it is safer to insist that the contract be under seal. The Public Health Act, 1875, s. 174 (1) provides that every contract made by an urban authority whereof the value or amount exceeds 50*l.* shall be in writing and sealed with the common seal of such authority. A surveyor who prepared plans for a local board under a verbal contract was held entitled to recover nothing (*Hunt* v. *Wimbledon Local Board* (1878) L. R. 4 C. D. 48). Close examination of a contract between an engineer and a local authority may, however, show that it is not within this section (see *Douglass* v. *Rhyl U.D.C.* (1913) 2 Ch. 407). Where the engineer is in the employment of a local authority he must have no interest in any contract into which that body enters (see *Melliss* v. *Shirley Local Board* (1885) L. R. 14 Q.B.D. 911). An attempt was recently made to raise the question whether a consulting engineer is liable to pay excess profits duty under s. 39 of the Finance Act, 1915, but the Court of Chancery refused to decide the point, leaving it to the King's Bench Division (*Smeeton* v. *Attorney-General* 35 T. L. R. 706).

(ii.) **Employment Abroad.**—Where an engineer is about to accept employment abroad, he should be careful to see that provision is made for the payment of travelling and other expenses. No agreement to pay travelling expenses would be implied from an undertaking, say, to employ an engineer at a salary of 1,000*l.* a year at Malacca as from January 1, 1913. It is also well to provide in the agreement that any disputes which may arise shall be determined either by arbitration or according to English law.

(iii.) **Wrongful Dismissal.**—If an engineer is wrongfully dismissed, it is his duty to reduce the damages as far as possible by taking other employment if he can procure it (see *Storey* v. *Fulham Steel Works* (1908) 23 T. L. R. 306). The damages are then ascertained by subtracting what he has earned from what he would have earned.

(iv.) **The Restrictive Covenant.**—When employing an assistant, an engineer may find it necessary to bind him not to set up close by in competition. A restrictive covenant is legal, if it is not too wide; it must be only what is reasonably necessary for the protection of the parties. A covenant to prevent a dentist practising within 200 miles of York was held to be too wide (*Horner* v. *Graves*, 7 Bing. 735). On the other hand, a covenant which bound a canvasser not to enter an employment 'within twenty-five miles of London where the plaintiffs carry on business' was held by the House of Lords to be unreasonable (*Provident Clothing and Supply Co.* v. *Mason* (1913) 29 T. L. R. 727). Care should be taken not to make the restriction perpetual unless that is absolutely necessary, for the Court criticises a perpetual covenant more closely (*Eastes* v. *Russ* (1915) 30 T. L. R. 237). In a recent case the validity of a covenant affecting a man who was employed as works engineer at a bottleworks was considered (*Forsters* v. *Suggett* 35 T. L. R. 87).

(v.) **Engineers and Compensation for Accidents.**—An engineer whose remuneration (*e.g.* money, board and lodging, etc.) amounts to less than 250*l.* in the service of an employer is probably entitled to the benefits of the Workmen's Compensation Act, 1906.

(vi.) **Engineers and the National Insurance Act.**—A nice question may arise as to whether, say, a station engineer must be treated as an employed contributor within the meaning of the National Insurance Act, 1911. That act covers employment in any contract of service subject to the proviso that persons earning more than 160*l.** otherwise than in manual labour need not be insured. It is submitted that the station engineer earning less than 160*l.* must be insured, but that the consulting engineer who receives an annual fee of 100*l.* for advising a firm or company need not be insured. His is a contract not 'of service' but 'for services'—a distinction which has been drawn in the Court of Appeal.

* By the National Health Insurance Act, 1919, now raised to 250*l.*

(4) SECRET COMMISSIONS.

The receipt of a secret commission or a bribe by an engineer would clearly justify his dismissal (*Boston Deep Sea Fishing Co.* v. *Ansell* (1888) 39 Ch. D. 339). In such a case there is a presumption that he was influenced, against his employers' interest, by the bribe (see *Hovenden* v. *Millhoff* (1900) 83 L. T. 11).

(5) DISCLOSURE OF SECRETS.

An engineer may be employed to do work of a confidential nature for others; or he may have to employ workmen to do confidential work for him (*e.g.* by employing a workman to make a model of a new and patentable machine). The law implies an agreement by the servant to keep his master's secrets, and he may be restrained by injunction from disclosing them (*Alperton Rubber Co.* v. *Manning and Others* (1917) 116 L. T. 499; 33 T. L. R. 205).

(6) RIGHTS OF AN ENGINEER TO THE INVENTIONS OF A SERVANT.

If a servant invents a machine in his employer's time and even when using his employer's materials, the invention does not become the property of the employer so as to prevent the servant taking out a patent for it (*Heald's Case*, 8 R. P. C. 430). But if the servant were to steal an idea and endeavour to patent it either before or after the termination of the service, the employer could oppose the grant of a patent in respect of it (*Thwaites' Application*, 9 R. P. C. 515). And if the servant obtains a grant of a patent in respect of the invention, he can only hold it as trustee for his employers (*British Reinforced Concrete Engineering Co.* v. *Lind* (1917) 33 T. L. R. 170). The engineer when employing a servant should take care to provide, by the agreement, that the inventions of the servant shall belong to him; but when himself entering into a contract of service he should be careful to sign nothing which will abrogate his rights.

(7) THE ENGINEER AS WITNESS.

(i.) **Generally.**—As the engineer frequently comes into contact with the law and the lawyers in the capacity of a *witness*, a few notes of a practical character on the duties of a witness may be found useful.

When invited to give evidence as an expert the engineer should: (*a*) arrange for a qualifying fee to be paid in any event; (*b*) examine the plans and documents, and, if necessary, obtain a view of the *locus in quo* before consenting to give evidence; (*c*) warn the parties consulting him of all the difficulties which are manifest to him; (*d*) ascertain, if possible, the contentions which are going to be put forward by the other side, and make himself familiar with any views which they may have published upon the matters in dispute. Having consented to give evidence, the engineer should (*a*) be ready to satisfy the lawyers with regard to any technical point which may be raised in consultation; (*b*) listen to the arguments and evidence in Court, and be prepared to deal with any points made by witnesses on the other side; (*c*) bring with him any entries in his diary or any notes which he may have made *at the time* with reference to the matters in dispute, for he may use such notes to refresh his memory. Thus, if an engineer has to report as to the condition of a structure, he may use in the witness box the notes which he made on the spot. But he could not use a copy of such notes unless he was prepared to produce the original; (*d*) make and bring to court a plan or model of the structure or machine under discussion, as this will save much wordy explanation; (*e*) search in libraries and in the published proceedings of the various institutions for any books and papers dealing with the matters in hand—especially any papers written by himself, in order that he may not be confronted with an adverse opinion given on a former occasion. A witness should bear in mind that it is his duty to state facts and express opinions, not to advocate the cause. As soon as he appears to be taking a biased view or attempting to fight the case it is more than likely that the tribunal will pay little heed to his evidence. A candid answer to an awkward question is often less dangerous than a long and evasive statement. In *Crosfield and Sons, Ltd.* v. *Techno-Chemical Laboratories Ltd.* (1913, 29 T. L. R. 378) Neville, J., expressed some views as to the function of an expert witness which may be thus summarised:—

(*a*) It is not competent in any action for witnesses to express their opinion upon any of the issues, whether of law or fact, which the Court or a jury has to determine.

(*b*) In patent cases, expert evidence is often necessary (i) to explain words or terms of science or art, or to inform the Court in case the import of a word in a document to be construed differs from its popular meaning; (ii) to instruct the Court in the laws of science; (iii) to describe the state of public knowledge at the date of the patent. 'It is rare,' added his lordship, 'to find any substantial difference of opinion between eminent experts upon matters of science whenever it is possible to dissociate the question from immediate connection with the issues in the action.'

(ii.) **Arrangements as to Fees.**—On being *subpœnaed* one is bound to attend as a witness provided sufficient conduct money is paid with the subpœna. Failure to attend might lead to an action for damages, while in the County Court the judge has power to fine a witness for non-attendance. A witness may refuse to give evidence until his expenses have been

paid (*Newton* v. *Harland* (1840) 1 M. & G. 956). It should be noticed that the person liable to pay the fees is the party to the litigation, not the solicitor, unless he has expressly made himself liable (*Lee* v. *Everest* (1857) 26 L. J. Ex. 334). In order to save trouble it is best to arrange for and if possible secure payment of fees in advance. The fees 'allowed on taxation,' that is to say, the fees which an unsuccessful litigant will be ordered to pay in respect of witnesses called by the other side, are very small, but the party calling the witness will have to pay his agreed fee whatever it is. Where a case is tried at assizes in the town where the engineer lives or in London (when the engineer lives in London), the fee allowed is 1*l.* 1*s.* *per diem*, or where the engineer lives away from the town 1*l.* 1*s.* to 3*l.* 3*s.* But the taxing masters may also allow a qualifying fee of so much a day varying with the magnitude of the case. In 1875 a fee of 7*l.* 7*s.* was not considered excessive payment to a scientific witness. It is probable that a larger sum would be allowed at the present day. In addition he is allowed the travelling expenses reasonably and actually paid. In County Courts the fee allowed for qualifying to give evidence on Scale B is 1*l.* 1*s.* to 3*l.* 3*s.*; on Scale C, 1*l.* 1*s.* to 5*l.* 5*s.*; for attending Court on trial (*per diem*), Scale B, 1*l.* 1*s.* to 2*l.* 2*s.*; Scale C, 1*l.* 1*s.* to 3*l.* 3*s.*

The above scales were fixed before the war, and have not been altered. So far as they can the taxing masters will probably grant the maximum owing to high prices.

(iii.) **Evidence before Parliamentary Committees.**—When an engineer is summoned to appear as a witness before a committee of either House of Parliament he looks for his fees to the party who summons him—whether he is the promoter or an opponent. According to May's 'Parliamentary Practice' (1906) p. 434, an engineer summoned as a witness before a committee should report himself to the committee clerk on his arrival in London, or he will not be allowed his expenses for residence prior to the day of making his report; 3*l.* 3*s.* a day is the parliamentary allowance, but of course as between the engineer and the party summoning him the *quantum* of the fee is a matter of agreement.

(8) LIABILITY FOR NEGLIGENCE.

The liability of an engineer for negligence is similar to that of any other professional man. To render him liable it is not enough that there has been a less degree of skill than some other professional man might have shown. A fair average degree of skill is all that can be insisted upon (*Lamphier* v. *Phipos* (1838) 8 Car. & P. 475). If an engineer were so careless in the preparation of a tender that the cost of the works was grossly underestimated, he would probably be liable to pay damages, and he certainly could not recover his fees (*Moneypenny* v. *Hartland* (1826) 2 C. & P. 379). An engineer should be acquainted with any local bye-laws appertaining to the work in hand (*Monks* v. *Dillon* (1884) 12 L. R. Ir. 321). On the principle of *respondeat superior*, an engineer is responsible for the acts or defaults of assistants employed by him (*Mackersy* v. *Ramsays* (1842) 9 C. & F. 818). The question 'To whom is the engineer liable for negligence?' depends upon the conditions of employment. If he is engineer in relation to a large contract, he is not liable for anything done by him in his capacity as arbitrator between the employer and the contractor; but he is liable for damage resulting from negligence in supervision, *e.g.*, failure to examine and test work before it is hidden from view (*Leicester Guardians* v. *Trollope* (1911) 75 J. P. 197). The contractor, however, could not sue the engineer for an error in the specifications on the basis of which he made his tender. Where, however, the 'quantities' are prepared by the engineer, and his fees for their preparation are paid by the contractor, it is conceived that he could be sued for damages resulting from an error in those quantities (*Bolt* v. *Thomas*, 'The Law Affecting Engineers,' p. 58). If an engineer order extras without authority, the contractor may possibly sue him for damages for breach of warranty of authority (*Randall* v. *Trimen* (1856) 18 C.B. 786). The amount of damages recoverable for negligence is to be measured by the loss which the plaintiff has suffered. In *Saunders* v. *Broadstairs Local Board* (1890) 2 H. B. C. 160, two engineers claimed fees for preparing surveys, obtaining tenders, and superintending the execution of a contract for certain drainage works. The board counterclaimed for negligence and were awarded 2,046*l.*, the amount overpaid to the contractor by reason of the negligence of the engineers in over-certifying the quantities; 2,400*l.* estimated cost of doing bad work over again; 240*l.* actual cost of repairs already done to defective work. Damages recovered by a workman against his employer for an accident might also be recovered from the engineer if it were shown that the accident was caused by the engineer's negligence (*Mosdell* v. *Mitchell*, 'Times,' January 20, 1891).

(9) RIGHTS, POWERS, AND DUTIES OF AN ENGINEER UNDER A CONTRACT FOR WORKS.

(i.) **Generally.**—Common forms of contract for large works usually set forth the powers, etc., of the engineer very clearly. The preparation of the contract is generally left to a lawyer, but the engineer should be on his guard against allowing a common printed form to be applied indiscriminately to the construction of works of a special nature. When difficulties arise it may be found that the common form does not provide for their elucidation.

(ii.) **Specifications.**—The contract should contain a clause providing that the employer will not be responsible for any mistakes or inaccuracies in the specifications which form part of the contract. Such a clause will, in the absence of fraud, afford him protection (*Pearson* v. *Dublin Corporation* (1907) A. C. 357). There should also be a clause calling the would-be contractor's attention to the fact that he must make surveys and borings for himself before making his tender. In that case, if unforeseen difficulties are met with the employer will not be responsible (*Thorn* v. *Mayor of London* (1876) L. R. 1 A.C. 120). Again, where a man undertakes to make *e.g.* sound hydraulic cylinders according to a specification, capable of withstanding a certain pressure, he takes upon himself the risk of the cylinders being able to withstand the named pressure when made according to the specification (*Hydraulic Co.* v. *Spencer* (1886) 2 T. L. R. 554). Carelessness in the preparation of a specification may involve the employer in added expense, for which the engineer may be liable (*Moneypenny* v. *Hartland* (1828) 2 C. & P. 378).

(iii.) **Plans and Drawings.**—These form part of the contract, and may, in the absence of a disclaiming clause, operate as a warranty that dimensions, measurements, etc., are correct. A clause disclaiming responsibility for accuracy should therefore be inserted in the contract. The engineer has no implied authority to alter plans and drawings so as to increase or lessen the burden imposed upon the contractor (*Cooper* v. *Langdon* (1841) 9 M. & W. 60). Delay in supplying the necessary plans and drawings may excuse the contractor from carrying out the work within the contract time (*Roberts* v. *Bury Commissioners* (1869) L. R. 5 C. P. 310). It is for the engineer who prepares them to see that they conform to local bye-laws (*Cubitt* v. *Smith* (1864) 11 L. T. 298). Plans and drawings made for the purpose of carrying out works are the property of the employer—not of the engineer (*Gibbon* v. *Pease* (1905) 1 K.B. 810). As to copyright in plans, see the Copyright Act, 1911, s. 5.

(iv.) **Extras.**—The duty of deciding what are 'extras' within the meaning of the contract is usually entrusted to the engineer. He has no implied authority to order extras (*Cooper* v. *Langdon* (1841) 9 M. & W. 60), although an agreement to work *to the satisfaction* of an engineer has been held to give him implied authority to order extras (*Robertson* v. *Jarvie* (1910) 45 S. L. R. 260). It has been held, however, that where the plaintiffs were employed by an architect (whose functions, for this purpose, correspond to those of an engineer) to supply door handles and door furniture for a building, and shortly before the delivery of the goods he informed the defendants, who were the builders, that the goods were being supplied by the plaintiffs, the defendants who used the goods in the building were liable to pay for them (*Ramsden* v. *Chessum* (1914) 78 J. P. 49). Extras should be authorised in the manner provided by the contract, which usually provides that all extras shall be ordered in writing (*Russell* v. *Saida Baudeira* (1862) 13 C. B. N. S. 149); but, in the case of a contract with a local authority, which must be under seal, the order for extras need not be under seal (*Williams* v. *Barmouth Urban Council* (1897) 77 L. T. 383). If a written certificate is rendered necessary by the contract, nothing else will suffice; but in a recent case a contractor proceeded with extra work as required by an engineer without any written order. On his claiming payment, an arbitrator found that the engineer was wrong and unreasonable, and that the work and materials required by him were not included in the contract. After much litigation the House of Lords eventually held that this decision was correct (*Brodie* v. *Cardiff Corporation* (1919) 120 L. T. 417). Although the whole scheme of works cannot be altered by virtue of the extra clause (*R.* v. *Peto*, 1 Y. & J. 37) power to *vary* the work will give the engineer authority to substitute one piece of machinery for another of which it is well known to be the mechanical equivalent (*Stevens* v. *Mewes & Davies*, Court of Appeal, June 7, 1910; Emden's 'Building Contracts,' Supplement 1911). The engineer should therefore see that he has power to *vary* the work. The engineer's decision as to what are extras may or may not be subject to revision in accordance with the arbitration clause. So far as the contractor is concerned, the fact that the engineer has given his final certificate (see *sub tit. Certificates, post*) may involve a final decision as to what is and what is not an extra (*Connor* v. *Belfast Water Commissioners* (1871) 5 L. R. Ir. C. L. 55). Power to extend the time for completion is generally given to the engineer. It may be that owing to the action of the Government acting under the Defence of the Realm Acts, the performance of a contract for works becomes illegal during the continuance of the War. In such a case it is conceived that no extension of time by the engineer will avail to keep the contract alive (see *Metropolitan Water Board* v. *Dick, Kerr & Co.*, 34 T. L. R. 111).

(v.) **Certificates.**—It is the duty of an engineer in relation to a contract for large works to grant or withhold the certificates upon which the contractor is paid. 'Progress certificates' are given from time to time as the work proceeds. They generally authorise payment to the extent of 80 per cent. upon the contract value of the work done from time to time. The remaining 20 per cent. is kept back usually, as to 15 per cent. until the final certificate is granted and as to 5 per cent. until the end of some stated period after the final certificate. This 20 per cent. is called the retention money (see *West Yorkshire Bank Ltd.* v. *Isherwood Bros.* (1912) 28 T. L. R. 593). The 'final certificate' is granted when the work is finished to the satisfaction of the engineer, and the contractor can sue for nothing until it has been granted (*Wallace* v. *Brandon and Byshottles U.D.C.* (1903) 2 H. B. C. 392). In deciding as to certificates the engineer acts as an arbitrator, and his decisions cannot be called in question (*Wadsworth* v. *Smith* (1871) L. R. 6 Q.B. 332); nor can he be compelled, and is better advised not to give reasons for his decision (*Stevenson* v. *Watson*

(1879) L. R. 4 C. P. D. 148). No action lies against him for negligence in relation to certificates (*ib.*) (but see the case of *Goddard* v. *Ferguson*, *infra*). In exercising his discretion he must act as an arbitrator between employer and contractor (*Chambers* v. *Goldthorpe* (1901) 1 K.B. 624). It may, however, be that the decision of the engineer as to a certificate is subject to the arbitration clause, which has been held to be the case in relation to the form of contract approved by the Royal Institute of British Architects (*Robins* v. *Goddard* (1905) 1 K.B. 294). A fraudulent agreement between the employer and the engineer would however affect the validity of a certificate (*Kellett* v. *New Mills U.D.C.* (1900) 2 H. B. C. 330). The certificate of the engineer may be made a condition precedent to the contractor's right of action against the employer. If so an action cannot be maintained unless there has been improper dealing between the engineer and the employer (*Eaglesham* v. *McMaster* (1920) 2 K. B. 169). The statement that an engineer is not liable for negligence in relation to a certificate does not appear to be supported by the case of *Goddard* v. *Ferguson* (referred to by Mr. Saxon Snell in a paper read by him at the Royal Institute of British Architects, April 15, 1912). It was there held that an architect who grants a certificate which is successfully challenged by an employer in an action brought against him by a builder to recover the amount so certified to be due to him, is liable to repay to the employer the costs incurred by him in resisting the builder's claim. The Official Referee held the architect liable on the ground that when acting as agent for the building owner in granting certificates, he must be held responsible for the reasonable and probable consequences of giving a certificate subsequently held to be inaccurate or excessive. Certificates should always be given in writing in a formal manner. No engineer should pass any contract which does not contain a provision to this effect. As to when an engineer is disqualified from granting certificates, see paragraph ix., *infra*. An engineer has no right to delegate the power to grant a certificate to a subordinate, *e.g.* to the resident engineer (*Freeman & Sons* v. *Middleton Electric Traction Co.*, per Hamilton, J., July 15, 1910; Court of Appeal, January, 1911; Emden's 'Building Contracts,' Supplement, 1911).

(vi.) **Penalties and Bonuses.**—The question whether the contractor must pay penalties or not depends almost entirely upon the engineer. Penalties are imposed if the work is not carried out in accordance with the provisions of the contract as to time. The fact that extras are ordered will excuse the contractor from compliance with the conditions as to time (*Dodd* v. *Churton* (1897) 1 Q.B. 562), but the jurisdiction of the engineer does not extend to deciding this point (*Gallivan* v. *Killarney Urban Council* (1912) 2 Ir. R. 356). To avoid complication, however, it is best to insert a clause in the contract giving the engineer power to extend the time. With regard to the penalty clause generally nice questions sometimes arise as to whether it is capable of enforcement. If it is unreasonable on the ground that the punishment is too severe, the Court may refuse to enforce it; and it is for this reason that the words 'the sums to be regarded as liquidated damages and not as a penalty' are usually inserted after the sum named. The breach of an engineering contract involves damage of so uncertain a nature that the courts will generally treat the sum which the parties themselves have named as liquidated damages. Penalties will not be imposed if (*a*) the delay was caused by the act or default of the employer (*Thornhill* v. *Neats* (1860) 8 C. B. N. S. 831); (*b*) if there is delay in setting out the site or in delivering plans (*Roberts* v. *Bury Improvement Commissioners* (1870) L. R. 5 C. P. 310). The fact that the contractor has been delayed by a strike of his workmen, however, affords no excuse for delay (*Budgett* v. *Rimington & Co.* (1890) 25 Q.B. D. 320), nor, apparently, is the employer to be held liable for the acts of third parties causing delay (*Porter* v. *Tottenham U.C.* (1915) 1 K. B. 776). While a penalty clause is usually optional, it is obligatory in contracts made with certain local authorities (see Public Health Act (1875) s. 174 (2)). A bonus clause is sometimes inserted by virtue of which a contractor is enabled so much extra for expedition. If a contract contains such a clause, and the engineer has power to extend the time, it seems that his power to extend must be exercised not to enable the contractor to earn the bonus but only to avoid penalties (*Ware* v. *Lyttelton Harbour Board* (1882) 1 N. Z. R. 191).

(vii.) **Defects, Repairs, and Maintenance.**—In contracts relating to the erection of machinery clauses should be inserted providing for any defects which appear either before or after the issue of the final certificate. A useful form of this clause will be found in the printed conditions of contract issued by the Institution of Electrical Engineers. Its importance will be recognised when it is pointed out that when it is absent the final certificate of the engineer may possibly bar any further claim by the employer (*Lord Bateman* v. *Thompson* (1875) 2 H. B. C. 23). The time for the remedy of defects should be prolonged as much as possible, inasmuch as the very fact of there being a defects clause impliedly releases the contractor from liability for defects appearing after the stated time (*Sharp* v. *Great Western Railway Co.* (1841) 11 L. J. Ex. 17). The contractor can only be called upon to repair and maintain when compelled to do so by a repairing clause and a maintenance clause. The employer must give notice of want of repair. Maintenance should be provided for in cases where the machinery or work is of a special character which is best known to the contractor. In the absence of any clause relating to defects and maintenance, it does not follow that on payment of the full price the employer thereby waives all claim for damages for work improperly done. It is a question of fact having regard to all the circumstances of the case whether the settlement was final and complete.

(viii.) **Subcontractors and Specialists.**—Most modern contracts involve the employment of subcontractors or specialists. A clause should be inserted in the head contract prohibiting the employment of any subcontractor or specialist unless approved by the engineer. In the absence

of such a clause, the contractor might, possibly, farm out portions of the work to all and sundry (*British Waggon Co.* v. *Lea* (1880) 5 Q. B. D. 149). The engineer, apparently, has no implied authority to employ subcontractors (*Cowan* v. *Goderich* (1859) 10 U. C. C. P. 87). It is often well to specify the names of manufacturers of the raw materials which are to be used in the body of the contract. In order to preserve his right to supervise the work of any subcontractor or specialist, the engineer should secure the insertion in the head contract of a clause providing that payments to subcontractors shall be made by the contractor only upon the certificates of the engineer. It is also well to secure the insertion of a clause to the effect that, in the event of the contractor becoming insolvent, the subcontractor or specialist may be paid directly by the employer. All responsibility for delay or negligence on the part of a subcontractor is generally, by a special clause, placed upon the contractor (see, generally, *Crittall* v. *L. C. C.* (1910) 75 J. P. 203; *Hampton* v. *Glamorgan County Council* (1916) 115 L. T. R. 426, and the case of *Ramsden* v. *Chessum*, cited, *supra*, s. (9) (v.) (i.)).

(ix.) **Whether the Employer's Engineer can act as Arbitrator in Relation to Disputes Arising under a Contract.**—The position of the engineer in relation to a large contract has been rendered very difficult by certain recent decisions of the courts. In theory he is agent for the employer in the preparation of plans and specifications and in the supervision of the work, and he is arbitrator or *quasi* arbitrator between the employer and contractor in granting certificates, approving work done, granting extensions of time, etc. Sometimes he is made sole arbitrator to decide all disputes between the employer and the contractor, and a serious question has arisen in several recent cases as to how far a contractor can be forced to accept his decision whether in the matter of granting certificates, etc., or as arbitrator. In *Jackson* v. *Barry Railway Co.* (1893) 1 Ch. 238, it was held that the fact of the employer's engineer having expressed a view of the matter in dispute hostile to the contractor was not a sufficient justification for refusing to allow him to act as arbitrator in relation to that dispute. The Court of Appeal pointed out that the contractors had agreed to this form of reference, and what they relied on was the professional honour, practice, and intelligence of the engineer. There was nothing in the circumstances of the case to render it improbable that he would not arrive at an honest decision.

In *Ives* v. *Willans* (1894, 2 Ch. 478) the same result was arrived at, although in giving judgment Lord Justice Davey said: 'No doubt in a sense the engineer will be the judge of his own conduct, and no doubt that is a position which *prima facie* raises some surprise in a judicial mind; but that is the contract of the parties.' As already indicated later decisions appear to have practically altered the law, although the judges always took care to say that *Ives* v. *Willans* is still good law. The result of the recent cases may be thus summarised. A contractor will not be bound to submit to the arbitrament of the employer's engineer (*a*) if the matter in issue is an unseemly personal dispute raising a vindictive feeling between the engineer and the contractor, and the engineer has so strongly expressed his view that it amounts to a prejudgment (*Nuttall* v. *Manchester Corporation* (1893) 8 T. L. R. 513); (*b*) if the nature of the dispute is such that the cross-examination of the engineer is essential (*Freeman* v. *Chester R. D. C.* (1911) 1 K.B. 783); (*c*) if the matter in issue is something outside the original agreement, e.g., a dispute as to whether the engineer and contractor had agreed to vary the original agreement (*Aird* v. *Bristol Corporation* (1913) A. C. 241); (*d*) if the conduct of the engineer himself is practically the only point in dispute (*Blackwell* v. *Derby Corporation* (1909) 75 J. P. 129). Finally, it was held in *Roberts* v. *Hickman* (1913) A. C. 229 that the grant of a certificate by an architect will not be a condition precedent to the builder's right to sue if, by writing letters to the employer, and allowing himself to be influenced by their views, the architect has disqualified himself from acting judicially although guilty of no fraud or improper conduct.

If the method of arbitration provided for in many existing forms of contract is declared to be impossible for any of the above reasons the only alternative is litigation, a method of settling disputes which employers, contractors, and engineers always seem to desire to avoid. What can be done to avoid such a calamity in relation to future contracts? The following courses are open. Insert a clause (*a*) referring all disputes to an arbitrator to be mutually agreed or to be nominated by the president of one of the Institutes (see, *e.g.*, the form approved by the Institution of Electrical Engineers, clause 47); or (*b*) referring disputes to a *named* arbitrator; or (*c*) refer disputes to the president of one of the Institutes whoever he may be. The first of these suggestions appears to offer the best practical solution of the difficulty. The writer, however, ventures to make the following suggestion which might possibly work in practice. Frame the arbitration clause so as to leave the decision of every question arising under the contract to the engineer but subject to a proviso that should it appear to the Court on an application to stay any action or proceeding brought in relation to the contract that the engineer is disqualified from acting as arbitrator the matters in dispute will be referred to an engineer to be agreed between the parties, or failing agreement to be nominated by the president of the Institution of Civil Engineers. Another alternative is suggested by Mr. E. J. Rimmer in his Arbitration Clause in 'Engineering Contracts' (Constable & Co.). It is that a proviso should be added to the arbitration clause stating that if any action is brought the defendant may either (*a*) have the action stayed or (*b*) have the matter referred to an independent arbitrator appointed in one or other of the manners above suggested.

(10) THE ENGINEER AS ARBITRATOR.*

(i.) **Generally.**—Engineers are frequently called upon to act as arbitrators to decide disputes of a technical nature wholly unconnected with any contract in which the engineer has been employed. Arbitrations are conducted in accordance with the provisions of the Arbitration Act, 1883. An arbitrator may be appointed (*a*) by the Court; (*b*) by the terms of the contract itself; or (*c*) by a person nominated for that purpose in the contract, e.g., the president of the Institution of Civil Engineers. As to appointment by the Court, this occasionally takes place when a prolonged scientific enquiry is necessary. A 'referee' of this kind may have power either to wholly dispose of the dispute or make an enquiry and report to the Court, in which latter case the Court itself gives the judgment after considering the report. As references of this kind are rare in practice they will not be further dealt with.

As a rule the engineer finds himself made arbitrator pursuant to the arbitration clause in an agreement. Any dispute arising under any contract may thus be referred, and the parties will as a general rule be bound to proceed to arbitration for the purpose of settling a dispute instead of bringing an action at law. Where a contract contains an arbitration clause, if one party commences an action, the other may apply to the Court to stay the action pending a reference, and the action will generally be stayed, unless there is some good reason for not allowing the arbitration to proceed. For instance, a contractor alleged that he had been induced by fraudulent representations as to the nature of the soil to enter into a particular sewerage contract, and brought an action for fraudulent misrepresentation. It was held that such an action ought not to be sent to arbitration (*Monro* v. *Bognor Urban District Council* (1915) 84 L. J. K. B. 1091). But the Court will stay an action, and allow an arbitration to proceed, although the question at issue is one which might be more suitably tried in a court of law—*e.g.* the construction of a contract (*Metropolitan Tunnel, etc.*, v. *London Electric Ry.* (1926) 1 Ch. 371). (See also par. 9 (ix.), *supra*.)

(ii.) **Who may be Arbitrator.**—Any person upon whom the parties agree may act as arbitrator. Thus if in a contract with a local authority it is specified that the borough engineer shall be arbitrator there is no objection to his so acting, and the contractor can be compelled to accept his award (*Ives* v. *Willans*, *supra*, 2 Ch. 478). That is the broad rule, but the Court, as has been shown, always has power to refuse to enforce the arbitration clause in a case where it is obvious that the arbitrator ought not to act owing to bias, etc. Frequently the clause provides for the appointment of an arbitrator by each party with power to the arbitrators in case of differences to appoint an umpire.† When this is done the umpire and arbitrators generally find it convenient to sit together to decide the case.

(iii.) **Proceedings before the Arbitrator.**—Witnesses must be sworn in the usual way. Due notice must be given to either party of the time when it is proposed to hold the sitting. In a case of great complexity it is well to have a preliminary sitting in order to require the parties to formulate the points in difference between them. By this means the issues may be considerably narrowed. The arbitrator should hear both sides, who may be represented by solicitor or counsel. He must never hold private communication with one party on the subject matter of the reference. He has no power to examine witnesses in the absence of the parties. An arbitrator who takes evidence in the absence of, and without notice to, a tenant, is guilty of legal misconduct, for which his award may be set aside (*In re O'Connor*, 88 L. J. K. B. 1242; *Ramsden* v. *Jacobs* (1922) 1 K.B. 640). It is for the arbitrator to decide every question whether of law or fact. He may, however, consult a solicitor or, for that matter, any other expert on legal points. Indeed the writer was recently concerned in a case in which, with the consent of the parties, the arbitrator had his solicitor sitting by his side. He should take full notes of the evidence, unless, as is frequently the case, the parties agree to have a shorthand note.

(iv.) **The Award.**—If the case is complex, the engineer is well advised to consult his solicitor as to the form of the award. The following are the features of a valid award, which should be in writing. (*a*) *It must not exceed the submission.* Thus if the question submitted was whether the stone used for building a dam was according to specification, the arbitrator would have no power to award that the stone used was better than as specified and that the employer must pay for it. (*b*) *It must extend to all matters in dispute.* If several distinct questions are referred and the arbitrator omits to decide upon any one of them, the whole award is bad. If in the case mentioned

---

* The Institute of Arbitrators, 28 Bedford Square, London, W.C. 1, and the Court of Arbitration of the London Iron and Steel Exchange, 28 Essex Street, Strand, London, W.C. 2, are always willing to suggest the names of qualified arbitrators with special technical knowledge. Reference to either of these bodies, therefore, tends to ensure that the arbitrator has the requisite technical knowledge as well as the legal knowledge and experience, which are so essential to the satisfactory conduct of an arbitration.

† An engineer who is appointed by one party to a dispute, the other party appointing another arbitrator, will usually find it advisable to nominate a Fellow of the Institute of Arbitrators with special knowledge of the subject in dispute as the umpire.

he were asked to decide (i.) was the stone as specified ; (ii.) was it suitable for the purpose, he would have to decide both questions. (*c*) *It must be certain.* The award must be so framed that its meaning is clear to the parties ; but according to a legal maxim, that is certain which is capable of being rendered certain. Thus to award that A. and B. shall pay a debt in the proportion in which A. and B. hold shares in a ship is a sufficiently definite award (*Watson* v. *Watson* (1671) Sty. 28). (*d*) *It must be final.* The award must peremptorily state the arbitrator's finding. A mere expression of opinion that A. ought to pay B. such sum as C. thinks proper would not be a final award. Finally (*e*) *it must not be impossible, unreasonable, inconsistent,* or *illegal.* An award which directed that one party should do something illegal, *e.g.* trespass upon the land of another, would be invalid.

(v.) **Time for Making an Award.**—In the absence of agreement, an award must be made (*a*) within three months of the date of entering on the reference, or (*b*) within three months after having been called on to act by notice in writing from one of the parties, or (*c*) on or before any later day to which the arbitrator may by writing under his hand extend the time for making the award (Arbitration Act, 1889, Schedule 1 (c)). The power to extend the time is important in the case of a long and complicated reference, but it must be exercised within the period of three months above referred to. Unless the arbitrator extends the time, or the parties agree to allow him to do so, an application must be made to the Court to extend the time ; and such an application may be made whether the time for making the award has expired or not (*ib.*, s. 9).

(vi.) **The Fees of an Arbitrator.**—The arbitrator should name his fee beforehand. It is best fixed at so much *per diem* for the hearing. If no preliminary arrangement is made, he is entitled to charge what is fair and reasonable, and he can keep back his award until the fees are paid (*Ponsford* v. *Swain*, J. & H. 433). When deciding in the award as to costs he should state who is to pay his fees ; but he may insist upon their being paid by the party who takes up the award. He should not reveal his decision until after these formalities have been observed. Sometimes the *quantum* of an arbitrator's fees is left to the decision of a taxing master. On such a taxation, if the evidence goes to show that, in the opinion of persons in the same profession as the arbitrator, that his charges are fair and reasonable, the taxing master must allow them. In *Mason* v. *Lovatt* (1907, 23 T. L. R. 486) a quantity surveyor was allowed to charge 527*l.* 10*s.* for a reference which lasted 22 days, the arbitrator subsequently taking 13 days to consider his opinion. In *Llandrindod Wells Water Co.* v. *Hawksley* (1904, 20 T. L. R. 241) the fees of an umpire and two arbitrators all being engineers were allowed at 476*l.* 12*s.*, in respect of a reference which lasted 2 days. The arbitrator should state how his fees are made up.

(vii.) **Stating a Case for the Opinion of the Court.**—Where a specific question is referred to an arbitrator, and he decides it, the fact that his decision is erroneous in point of law does not make the award bad on its face so as to admit of its being set aside (*In re King and Duveen* (1913) 2 K. B. 32) ; nor will the mere fact that the dispute involves questions of law induce the Court to stay a reference to arbitration (*Rowe* v. *Crossley* (1913) 108 L. T. 11). But where a point of law arises during a reference, the arbitrator, if he does not care to decide it, may state a case for the opinion of the Court (Arbitration Act, 1889, s. 19), or the Court may compel him to state a case (*ib.*). He can also make his award in the form of a special case, leaving it to the Court to decide how the judgment shall be entered. Refusal to state a case may constitute misconduct on the part of an arbitrator (*Czarnikow* v. *Roth Schmidt & Co.* (1922) 38 T. L. R. 595).

(viii.) **Costs of a Reference.***—On the question of costs, and as to the form of that part of his award which relates to costs, an arbitrator should consult his solicitor, because (*a*) highly technical questions arise with regard to costs and their taxation which no layman can be expected to understand, and (*b*) it is desirable that in this matter an arbitrator should observe as nearly as possible the principles which are recognised in courts of justice. Again, the defendant in the proceedings may have preferred a counter-claim in which he may have been successful wholly or in part. This further complicates the question of costs. It may be observed that there is no objection to an arbitrator employing a lawyer to advise him in the matter of costs or with reference to any other question which arises in a reference. The importance of taking this course is that a layman has not, and in the nature of things cannot have, the same mental outlook as a court of justice in dealing with the question of costs. Let a recent example suffice. An arbitrator made an award of £200, but as the plaintiff had claimed £1,200 and only succeeded as to £200, he made each side pay its own costs. In the result the plaintiff got less than nothing at all, as his costs far exceeded £200. Such a decision as to costs was, from a lawyer's view-point, entirely wrong. The arbitrator wholly overlooked the fact that the plaintiff was compelled to sue to recover

* The Court of Arbitration of the London Iron and Steel Exchange, 28 Essex Street, Strand, London, W.C. 2, has a simplified Scheme of Arbitration whereby if the necessary documents are placed before the arbitrator and no hearing is required, a fee of only two to five guineas is charged. This scheme is only applicable to simple cases ; further particulars can be obtained from the Secretary of the Exchange.

anything at all. In any event, and whether a solicitor is employed or not, the question of costs should be carefully considered, as the expenses of a reference are often wholly out of proportion to the sum in dispute. In litigation the general rule is 'costs follow the event'—an application of the maxim *vœ victis*. Unless the submission contains some special term as to costs, the arbitrator has full power to decide who is to pay them. He may award costs to be taxed 'as between solicitor and client'—which means that the successful party is nearly indemnified—or he may award costs to be taxed as between litigants in the ordinary way. He may also, in his discretion, award a fixed sum for costs (Arbitration Act, 1889, Schedule I. (i)), or he may declare that each party shall pay his own costs. In deciding whether to make a defendant pay costs, the arbitrator should (it is submitted) consider the nature of any offer made before the proceedings were commenced. Thus supposing a contractor claimed 5,000*l.* and the building owner made a firm offer of 4,000*l.* which was refused. After hearing the evidence, the arbitrator awards 4,000*l.* or less. In such a case he would be justified in disallowing the contractor any costs. An arbitrator can only make a successful plaintiff pay costs in exceptional circumstances as when (*e.g.*) it appears that although successful he should not have prosecuted his claim. It was held, however, in a case arising under the Small Holdings Act, 1908, the arbitrator in the exercise of his powers under that Act had wider powers in the matter of costs than a High Court judge (*Gray* v. *Baron Ashburton*, 115 L. T. R. 729).

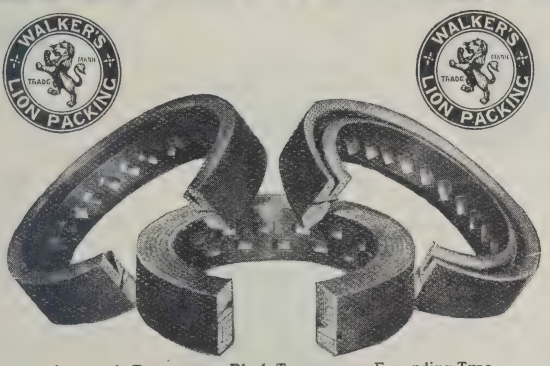
(11) NOTES ON SALE AND PURCHASE OF MACHINERY.

The question which most frequently arises on the sale of machinery, motor cars, etc., is what is the warranty of fitness? Sometimes, of course, there is an express written warranty, but in the absence of that the matter is regulated by section 14 of the Sale of Goods Act, 1893, which provides (in effect) that there is no implied warranty or condition as to the quality or fitness for any particular purpose of goods supplied under a contract of sale, except (1) where the buyer expressly makes known the purpose for which the goods are required so as to show that the buyer relies on the seller's skill or judgment and the goods are of a description which it is in the course of the seller's business to supply (whether he be the manufacturer or not) there is an implied condition that the goods shall be reasonably fit for such purpose; provided that in the case of the sale of a specified article under its patent or other trade name, there is no implied condition as to its fitness for any particular purpose; (2) where the goods are bought by description from a seller who deals in goods of that description (whether he be the manufacturer or not) there is an implied condition that the goods shall be of merchantable quality; provided that if the buyer has examined the goods there shall be no implied condition as regards defects which such examination ought to have revealed; (3) an implied warranty or condition as to quality or fitness for a particular purpose may be annexed by the usage of trade; (4) an express warranty or condition does not negative a warranty or condition implied by the Sale of Goods Act unless inconsistent therewith. The result of these provisions is that in certain cases the vendor is made liable for latent defects, that is to say, for defects which would not be discoverable on an ordinary examination of the article. Sometimes a contract for the sale of machinery contains provisions for payment of the price by instalments after production of the certificate of the engineer that such instalments are due and payable. It was held in a Scotch case (*Howden* v. *Powell Duffryn Steam Coal Co.* (1912), S. C. 920, Ct. of Sess.) that where, in such circumstances, part of the machinery was rejected, but the manufacturers refused to accept the rejection, the production of the engineer's certificate was not a condition precedent to the right to recover payment.

In the case of an engine which is attached to the freehold, a question may arise, on a sale, as to when the property passes. In *Underwood Ltd.* v. *Burgh Castle Brick and Cement Syndicate* (1922, 1 K. B. 343), a horizontal condensing engine was sold at a price free on rail, London. It was bolted to and embedded in a flooring of concrete. Before it could be delivered on rail it had to be detached and dismantled. The sellers detached it, but in loading it on a truck they damaged it by accident so that the buyers refused to accept it. In an action by the sellers for goods bargained and sold it was held that the property in the engine had not passed to the buyers, inasmuch as the sellers had failed to do something necessary to put it in a deliverable state. Consequently the loss fell on the sellers and not on the buyers.

PATENT

"LION" PACKING



Automatic Type Block Type Expanding Type

Reliable Packing for all Pressures

"LION" AUTOMATIC Packing for all Hydraulic work. It functions like a ram leather, and will stand the highest pressures.

"LION" BLOCK Packing for general purposes and for use under solid metal rings.

"LION" EXPANDING Packing for High Pressure and Superheat Steam work. Automatic in action, and a very popular type of Packing.

The KING of PACKINGS

JOINTING A SPECIALITY

Write for Catalogue No. 161.

JAMES WALKER & CO. LIMITED

"LION" WORKS, WOKING, Surrey.

'Phone : Woking 1040. 'Grams : "Lioncello."

LOC

Locomotive fireboxes, life of, 601
—— —— flexible wheel base, 599
—— —— frames, steel for, 618
—— —— fuel consumption, 624
—— —— injectors, 609
—— —— jointings, copper, Hulburd's, 608
—— —— link motion, 594, 1758
—— —— motion work, 593
—— —— oil, lubrication, consumption, 624
—— —— smoke boxes, 601
—— —— straight axles, 611
—— —— superheaters, 600, 601
—— —— tenders, 625
—— —— tubes, 600, 616
—— —— types, 572, 578
—— —— tyres, 597, 612
—— —— water consumption, 624
—— —— —— troughs, 625 [249, 252
—— —— weight distribution on bridges,
—— —— wheel base, flexible, 599
—— —— wheels, 597
—— —— —— counterbalancing, 599
Locomotives, 571
—— —— adhesion of, 587
—— —— alloys for parts of, 620
—— —— , American, 576
—— —— brass tubes for, 616
—— —— British, recent additions to, 571
—— —— general types, 572, 578
—— —— tank, 574, 578
—— —— tender, 572
—— —— bearing surfaces of, 596
—— —— castings for, 615
—— —— compound cylinders of, 592
—— —— , 592
—— —— cylinders of, 592
—— —— consumption of fuel in, 624
—— —— water in, 624
—— —— copper plates for, 615
—— —— rods for, 615
—— —— tubes for, 600, 616, 617
—— —— coupling rods of, 593
—— —— crank axles of, 596, 611
—— —— cylinders of, 592
—— —— simple and compound of equivalent power, 592
—— —— design of, 579
—— —— electric, 676, 2602
—— —— for light railways, 553
—— —— examination of, in running
—— —— forgings for, 615 [sheds, 625
—— —— Great Western Railway, 574, 576
—— —— horse-power of, 587, 589
—— —— iron castings for, 619
—— —— liquid fuel for, 620
—— —— London Midland and Scottish Railway, 572, 574
—— —— London & North Eastern Railway, 572, 574
—— —— lubricating oil consumption in,
—— —— 'Mallet,' 581 [624
—— —— mechanical stokers, 622
—— —— mine, 2602
—— —— motion work of, 593
—— —— parts of, 592
—— —— power of, 587
—— —— pulverised coal for, 622, 2141
—— —— —— peat for, 2142

LOW

Locomotives, regulators, Hulburd's, 601
—— —— relation of power to weight, 589
—— —— resistance of, 586
—— —— Southern Railway, 574, 576
—— —— speed of, 586
—— —— springs of, 613
—— —— steel castings for, 615
—— —— forgings for, 615
—— —— plates for, 617
—— —— tubes for, 616
—— —— storage battery, 707
—— —— straight, axles of, 611
—— —— superheaters, 600, 601
—— —— tank, 574
—— —— tender tools for, 625
—— —— tractive force of, 587, 592
—— —— tyres for wheels of, 597, 612
—— —— valve gear, 594
—— —— valves of, 593
—— —— weight of, 589
—— —— —— restriction in, 589
—— —— wheel base of, 599
Log frame-saw roller bearings, 973
Log-line, 1
Logs, storing, 360
—— to cut stoutest beam from, 357
—— —— stiffest beam from, 357
London Midland & Scottish Railway carriages, 628
—— —— —— locomotives, 572, 574

'THE ENGINEER'S YEAR-BOOK' CLASSIFIED DIRECTORY OF LEADING ENGINEERING AND ALLIED FIRMS ADVERTISING IN THE 1931 EDITION.

A RELIABLE GUIDE FOR THE USE OF BUYERS OF ENGINEERING MATERIALS, MACHINERY, TOOLS, PLANT, APPLIANCES, ETC.

For Advertisers' Addresses, and Positions of their Announcements in the 'Year-Book,' consult foregoing Alphabetical List, pages 2989 to 2997.

The aim of the Proprietors of 'The Engineer's Year-Book' is to include in this publication only the most reputable firms' announcements, so that readers desiring to order, or specify, the various specialities advertised, may do so with confidence.

CLASSIFIED DIRECTORY OF ADVERTISERS' MANUFACTURES AND SPECIALITIES.

With
Demag
Products
you work quicker
and cheaper—
You save time
and wages.

We are suppliers of:

ALL KINDS OF MACHINES FOR ROAD MAKING,
RAILWAY CONSTRUCTION AND TUNNEL BUILDING

Demag Universal Shovel Excavator, Type U, for the rapid removal of large quantities of earth, also for working in quarries.

Demag Scraper Plants, the most practical and simple conveying device for removing dumps and making cuttings.

Demag Motor Compressors, single- or double-axle, the light portable compressed-air producer with direct motor drive.

Demag Pneumatic Tools, for all purposes and for every industry, Drill Hammers, Riveting- and Chisel-Hammers, Concrete Breakers. Ask for our illustrated catalogues. Also regarding Large Volume Compressors, Toothed-wheel gears, Machinery and Hauling Engines for mines.

DEMAG Aktiengesellschaft DUISBURG

British Agents for Excavators, Steam Cranes and Gears

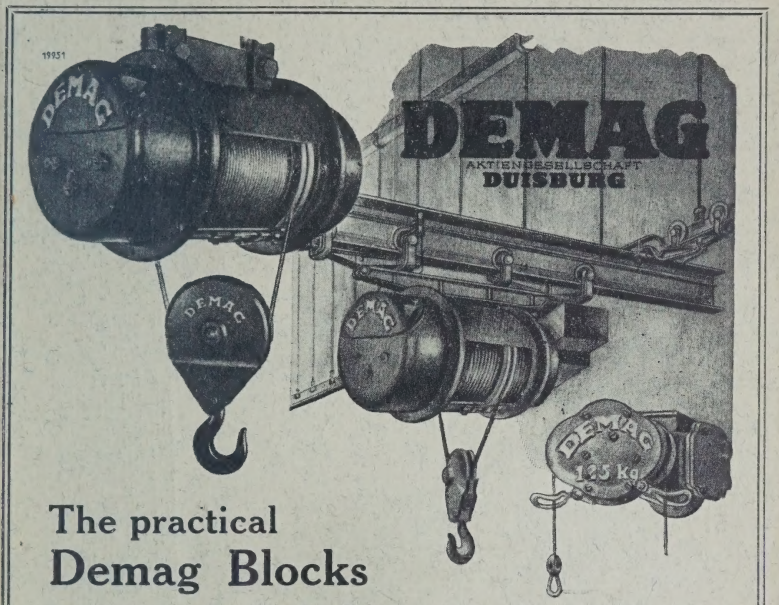
MAURICE WARLOW & Co.

12 Victoria Street, London, S.W.1, England

British Agents for Air-Compressors

THE ROTARY AIR COMPRESSORS Co., Ltd.

12 Victoria Street, London, S.W.1, England



The practical

Demag Blocks

are now operating in thousands in all the industrial countries of the world.

We are suppliers of:

MODERN ELECTRIC HIGH-SPEED HOISTING DEVICES AND TRANSPORTING PLANTS OF ALL KINDS

Demag Blocks, Model K, new construction with considerable improvements, they work quicker, easier and cheaper.

Demag Suspension Cranes (Patented), the new, practical crane construction design, with which the runways can be assembled by the customer's staff, as they consist of standardized parts.

Demag Double-acting Hoists (Patented), with 2 load hooks, 250 kg. carrying capacity, the small, practical lifting device for sacks and cases.

Demag Steam Cranes, running on narrow gauge track, for quick transport, working in factories and on stockyards. Write for our illustrated catalogues, including those for modern harbour cranes, level luffing cranes, loading bridges, shipyard cranes, floating cranes, factory overhead travelling cranes and cranes for other special purposes.
